to their work, which is easily effected by giving them half proportions of corn, or any food to their liking, several times in the day, first near the pond, next a rod or two distant, accompanied with the usual kindness or chucking at feeding times; then again, further and further, here a little food and there a little; thus by degrees they will traverse constantly and regularly a whole garden, or field, or farm, in search of food and slugs, provided those small rations of food are regularly laid here and there daily, without omission. By the usual wheedling and feeding at night they are easily enticed to their resting place, where, if preferred, an entrance just large enough for them to creep out at, may be left for their exit at day-break, in order that they may search for food. Care must be taken that the entrance is not large enough to admit dogs, foxes, etc. If they can be trusted out, they will prefer to rest and thrive best in the pond or sedges by nights, to be off betimes in the morning, when the slugs are out feeding. *Hardy and Son, Maldon. Gard. Chron. November 27 1852.*

The Week's Work.

THE ORCHID HOUSES.

By J. T. BARKER, Dunstable, Bedfordshire.

Pleiones.—The Indian Crocuses, as these Orchids are often named, are of easy culture, and few, if any, of our smaller Orchids make a more beautiful display in their respective seasons. Considering the quantity of flowers they produce, and their beautiful effect for decorative purposes, it is a wonder they are not more generally grown. The flowers last a considerable time in good condition, even when used for room decoration, whilst the individual blooms are useful for buttonholes. *P. maculata*, *P. lagenaria*, *P. concolor*, *P. praecox* and *P. Wallichiana*, are now passing out of flower, and the green shoots from which the blooms have sprung will, under proper treatment, develop into strong, flowering pseudo-bulbs. So soon as the flowers have faded, the new shoots will already have produced from their bases a number of small, white roots, and as these roots lengthen rapidly, no time should be lost before undertaking the necessary repotting; if the operation is delayed many of the roots will be injured, as they are easily broken, and thus a severe check will be given at a critical period. Shallow pans are the best receptacles, as they are easily suspended from the roof, and the plants need plenty of light, especially during the short days of winter; but care must be taken that they are hung far enough away from the glass to secure them from harm. The pans should be well-drained to permit the free passage of water through the material when the plants are in full growth. Pans of eight inches to ten inches in diameter, holding about eighteen to twenty pseudo-bulbs, will be suitable. Instead of dividing the growths, it is advisable to place them in clumps, allowing the pseudo-bulbs to almost touch each other, as a much better effect is then produced when they are in bloom than when the pans are scantily filled. The potting material should consist of equal parts of fibrous loam, peat and Sphagnum-moss, well mixed together, with the addition of a fair quantity of coarse silver sand. Over the crocks place a layer of moss to prevent the finer parts of the compost entering the drainage, then fill the pan to within an inch of the rim with the compost, on which the plants should be placed, the spaces between them and the sides of the pan being filled with compost. When filling in around the bulbs it is desirable to work in some heads of Sphagnum-moss, as growing moss provides wholesome moisture around the plants.

THE KITCHEN GARDEN.

By R. H. CROCKFORD, Gardener to THE RT. HON. LORD WAVERTREE, Horsley Hall, Gresford, N. Wales.

Celeriac.—The stump-rooted Celery, when fully grown, should be carefully lifted, have its leaves trimmed off and the roots stored in sand in a cool shed. Treated in this way the roots are kept free from frost and will remain fresh and sound for a considerable period. Where a large quantity is still growing in the open, it will be wise to protect the stock with Bracken, leaves or straw.

Endive.—After this date Endives cannot be relied upon in the open, and any that are still growing there should be lifted and placed closely together in frames, unless some other means of protection can be afforded; wattle hurdles with mats placed over them will be suitable, while old lights that can be spared, raised sufficiently over the plants and darkened with straw or litter, answer the purpose, and will blanch as well as protect the heads.

French Beans.—Where an average night temperature of about 60° can be maintained, successive batches of this useful vegetable should be sown, either in pots or frames. They

should be grown as near the glass as possible so to catch every ray of light. Where Beans are now carrying crops very careful watering and gentle feeding must be practised. An occasional syringing on warm days will prove beneficial. Close the house early in the day to husband all solar warmth possible. Keep the atmosphere of the house fairly humid and be always on the watch for white fly and thrips, vaporising the structure so soon as these pests are seen. In houses where plenty of head room is possible the climbing varieties of French Beans are very productive. Where pods of these varieties are growing freely, light dressings of Clay's Fertiliser sprinkled on the surface of the soil, and watered in with water at the same temperature as the house, will prove invaluable for assisting further production. Ventilation should be given whenever the outside conditions are suitable, taking care that cold draughts do not enter the house.

Cold Frames.—Parsley, Lettuces, Endives, Carrots, Cauliflowers, etc., growing in cold frames should receive an abundance of air, removing the lights entirely during suitable weather. The occupants should also be kept scrupulously clean, and have the soil stirred between them frequently. Slugs should be sought for and destroyed. During very severe weather the lights should be well covered at night with mats or other protecting material.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to SIR CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Violets.—Since being placed in the frames, Violets have made excellent progress and are now producing flowers in fair quantity. Violets dislike coddling at any time, therefore keeping the frames closed continuously will only end in failure. The lights should be drawn back so far as possible whenever the outside conditions will allow, and at night, except during frost, ample ventilation should be afforded. Remove all decaying foliage, frequently loosen the soil between the plants, keep all runners removed as they appear, and watch carefully for mice and slugs, which must be trapped.

Winter-flowering Begonias.—These are now making a bold display, and in the case of plants that have been removed to the conservatory, a little care is necessary with regard to watering. *B. Gloire de Lorraine* and its varieties are more suitable for foggy areas than *B. Optima* and *B. Mrs. Heale*, but these delightful winter-flowering Begonias should be grown in districts that are not liable to fogs.

Camellias.—Plants that have set their flower buds thickly should be disbudded. Take care that the plants do not suffer for lack of moisture at the roots, otherwise bud dropping will result; on the contrary, too much water is liable to cause similar trouble.

Propagating Chrysanthemums.—Certain Chrysanthemums that are grown to produce large exhibition flowers demand a long season of growth. These include such varieties as *Majestic* and its sports, *Mrs. G. Drabble*, *Wm. Rigby*, *Victory*, *Queen Mary*, *Princess Mary*, and *Mrs. J. Gibson*. In their case, early propagation is necessary. The cuttings may be inserted singly in small pots, or three may be inserted in a small sixty-sized pot. Where space is limited, the latter method will be found most convenient, and provided the young plants are potted off singly so soon as roots are formed, equally good results will be forthcoming as with those rooted singly. The pots should be filled with an open compost, and when the cuttings are inserted a watering should follow immediately to prevent the cuttings from flagging. Stand the pots of cuttings in a propagating frame in a cool house. It is a great mistake to attempt to root Chrysanthemums in heat. Many good varieties are very shy in producing cuttings, and when this is the case it is a good plan to shake the greater part of the soil from the old roots and repot them in a light compost; the newly-potted plants

should then be grown in a minimum temperature of 56°, when they will, in most cases, produce strong shoots suitable for use as cuttings.

HARDY FRUIT GARDEN.

By H. MARKHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet, Middlesex.

Orchard Trees.—The present is a very suitable time to deal with fruit trees in orchards. Thin out the heads where they are crowded with useless wood. This work is frequently left until after the leaves have fallen, but it may be carried out safely soon after the fruits have been gathered. In the case of old and much neglected trees, do not thin the heads excessively, but remove some of the crowded branches and repeat the operation next season. By keeping the tree moderately thin both crop and quality will be greatly improved. Some attention must, however, be paid to the habit of the tree. Varieties with rather weak and pendulous growth should not be too severely thinned, otherwise, when a very heavy crop is produced a goodly portion of the fruits may become much bruised during windy weather. When pruning large trees it is a good plan to have one man in the tree sawing out the branches and another below the tree giving directions to the pruner. After pruning, dress the land with farmyard manure, or replace the top spit of soil with fertile loam and bone-meal.

Plums.—In order to obtain the best results from Plum trees it is necessary that the trees should possess plenty of fibrous roots growing in suitable soil and sufficiently near the surface to be influenced by the sun's rays and an occasional top-dressing. There are numerous good varieties of Plums that succeed well when planted on east or west walls, grown either as cordons or trained fan-shape. Where the land lies somewhat low the borders should be raised above the level of the surrounding ground. The drainage should be good and the soil sweet and fertile. Add plenty of old mortar, a little bone-meal and burnt earth, and if the soil is of a less fertile character, decayed manure should be added. There are several good Plums that deserve a space against a wall. *Belle de Louvain*, *Early Transparent*, *Coe's Golden Drop*, *Kirke's*, *Jefferson*, *Victoria*, *Oullins*, *Golden Gage*, *Washington*, *Grand Duke*, *Deniston's Superb* and *Monarch*, the last a very large late cooking Plum, are all suitable. Do not nail in too much wood when training the trees, or employ more nails and shreds than are necessary, but retain young growths at intervals as these usually crop well the second season. Be careful not to bruise the bark when nailing, and see that all old ties are removed if they are injuring the bark.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to COLONEL SPENDER CLAY, M.P. Ford Manor, Lingfield, Surrey.

Figs.—Early Fig trees have not experienced a good season for ripening their wood, but they should now be in condition for starting about the end of November, that is where ripe fruits are needed in May. Pot trees are most in favour, and for very early fruits they are preferable to permanent trees—not that the crops they produce are better—as they may be moved as needed, or changed in the event of failure. Trees for starting in the present month must be thoroughly ripened and well-furnished with embryo Figlets; they should be fairly root bound—a condition which can only be secured by repotting very early in the autumn. If these essentials are not present, an early start will be useless. See that the drainage is correct. Carefully clean the stems with tepid, soapy-water taking care that the young Figlets are not scratched in the process. If worms are suspected a watering with lime-water will dislodge them. Bottom-heat being an important factor, the pits should be deep enough to allow about two feet of fermenting material composed of fresh leaves and stable manure. Place pots or bricks beneath the pots so as to raise the plants well up to the light. Frequent moderate waterings are necessary to get the soil and roots into good condition by the time the fermenting

material becomes warm and the house is closed for starting the Figs. Those wishing to commence forcing may secure good pot trees from the leading nurserymen, and as such trees should improve each year they are a good investment.

Figs in Successional Houses.—Trees in confined borders should be cleansed and put in working order. If the wood is young, soapy water and Gishurst compound should be used to clean the trees; all suspicious parts on old trees should be treated with pure Gishurst compound. When the trees have been dressed and trained the house may be kept dry and cool until the time arrives for forcing, and then the roots must be thoroughly moistened and fermenting material introduced. Trees which are grown in cold houses and only mature one good crop each season, may be kept in good fruiting condition by annual root-pruning, the use of sound, but not over rich, compost, thin training, and as good a roasting as possible by sun-heat in the autumn.

Cucumbers.—Late plants put out after October Melons will be rather more backward than usual, but will come in useful when the plants now in bearing are on the wane. Much depends upon the start, as these plants will keep on growing in a minimum of 60° and a maximum of 70°, with a brisk bottom-heat of 75° to 80°, especially if fermenting material is the main source of heat. Such plants should need very little pinching until the commencement of the year.

THE FLOWER GARDEN.

By JOHN COUTTS, Assistant Curator, Royal Botanic Gardens, Kew.

Plants for Shady Places.—In shady situations, such as under trees, it is often a difficult matter to keep the ground furnished. In the case of large trees on lawns nothing looks better than grass growing right up to the trunk, and this may generally be achieved by keeping the bottom branches clear of the ground. The surface soil should be pricked over and a top-dressing of fresh soil raked in; by this means and using a mixture of grasses that flourish in the shade one may generally keep the ground furnished. In other positions where it is desired to have a carpet of evergreen plants, Ivy may be relied upon to grow, even in dense shade. *Ruscus aculeatus* (the Butcher's Broom) also succeeds under the shade of trees, and it makes a good, bold edging for shrubberies, while the smaller *R. hypoglossum* may also be used for the same purpose; this also makes a good carpet under tall-growing shrubs. *Berberis Aquifolium* is invaluable for furnishing areas under thinly-planted trees, and by shortening the longer shoots it may be kept to any desired height. *Euonymus radicans* and its variegated variety are invaluable for carpeting shady places under trees. These make a good, bold edging to paths in the less dressed parts of the garden, but when used in this way they usually require clipping twice a year. The Periwinkles—*Vinca major* and *V. minor*—are also commonly used for furnishing shady places, and are excellent for covering steep banks; there are several varieties of each, including variegated forms. *Lonicera pileata* is a newer plant that is excellent for shady spots. *Sarcococca humile*, *S. ruscifolia* and *S. Hookeriana*—the last only hardy in the south—with small, white, sweetly-scented flowers, might be more generally grown, especially in the partial shade of large shrubs. *Gaultheria Shallon* and *G. procumbens* are also excellent for the same purpose. *Hypericum calycinum* is invaluable for covering banks, or for planting in shady places, but to keep it close and thick it should be cut over with a scythe every spring. Where larger-growing subjects are required, Box, Yew and Holly are always useful, but *Aucubas* and *Laurels* are much too freely planted in many gardens, and they do not present the same cheerful appearance as our native evergreens. *Funkias*, *Anemone japonica* and its varieties, as well as many other hardy herbaceous plants do fairly well in the shady margins of shrubberies; *Lily-of-the-Valley* will also succeed in similar situations and should be planted more freely in woodlands. *Epimediums* also do well in

partial shade. Many of the stronger-growing hardy Ferns are seen at their best in shady spots, and with them may be associated a host of bulbous and other plants.

FOR NORTHERN GARDENERS.

By A. T. HARRISON, Gardener to the MARQUIS OF AILSA, Culzean Castle, Maybole, Ayrshire.

Pruning Bush Fruits.—The pruning of Gooseberries and Currants may now be completed, and where the former are required to produce only a medium crop of large fruits for dessert purposes, close or spur-pruning may be practised, but where the aim of the cultivator is to produce a heavy crop, either for home supplies or for marketing, it is a mistake to remove too many of the current season's shoots, unless they

at an early date, removing all spent flower-stalks at the same time. Jerusalem Artichokes have been severely treated by the autumn winds, and their long stems are lying at every angle. These should now be cut down to a foot or two above the ground and cleared away. Where the roots are in great demand a supply may be lifted and stored in sand, but they are best left in the ground and lifted as required.

Rhubarb for Forcing.—Crowns of Rhubarb which have been prepared by lifting and exposure to the recent frosts may now be placed in the forcing house, packing them in as closely as possible with a mixture of soil and manure around them. A good watering with tepid water should be given to settle the bed, and a moderate temperature of 45° to 50° maintained for the first week or two, until

FIG. 191.—CHRYSANTHEMUM ALBION.

N.C.S. First-Class Certificate, November 14. Flowers white. Shown by Mr. H. Shoesmith, jun. (see p. 414).

are overcrowded. Remove all branches that are near the ground, as these are weighed down when carrying a crop and the fruits become splashed and unsightly during wet weather; after this, treat the bushes in much the same manner as recommended for Black Currants, by removing old, exhausted shoots and retaining so many of the young ones as space will allow. If Gooseberry mildew was prevalent the tips of the current season's shoots should have been removed during September, and the bushes sprayed with a fungicide, such as Burgundy mixture, or a solution of potassium sulphide. While pruning Black Currant bushes, a close watch should be kept for symptoms of reversion and big bud, and if the latter is found, the infested plants should be marked and either removed entirely or treated during the spring months to a regular course of spraying with lime sulphur.

Artichokes.—Globe Artichokes require additional protection to that supplied by their own foliage, and this, in the form of strawy manure, should be placed around the plants

growth has started, when, if necessary, the temperature may be raised and the growth accelerated, but Rhubarb of the best quality is produced when only a moderate temperature is maintained throughout, and plenty of luke warm water supplied when necessary.

Tigridias.—Except under the most favourable conditions, it is necessary to lift Tigridias annually and store them in a dry place for the winter, but where they are a success they should not be disturbed; the most suitable position for them is a well-drained border at the foot of a south wall or in front of a greenhouse. These gorgeous flowers are worth a little trouble, for although the individual blooms are short-lived, a succession is produced from the same spathe, and the splash of colour made by a good clump is most effective. When other means of flowering Tigridias successfully have failed, they may be grown in pots or pans in a cold greenhouse, where the roots may be kept dry, without disturbing them, after the foliage has died down.

BULB GARDEN.

EUCOMIS.

THE species of *Eucomis* are natives of the Cape, and although they are not the most effective or graceful members of the Lily family, they are deserving of cultivation in the outdoor garden on account of their broad, handsome leaves, more or less spotted with purple at the base, and their tall, cylindrical spikes of blossoms, surmounted by a crown of leaf-like bracts. Like so many other Cape plants, the *Eucomis* are hardy on light soils. The genus includes about eight species. The foot of a south wall is the ideal position in which to grow them, but the roots will require protection during the winter months.

E. undulata has leaves about eighteen inches long, with flower spikes three to four feet high. *E. punctata* is the largest, with leaves three feet long, while *E. regia* is quite dwarf, with racemes of flowers one foot high. *E. nana* is the smallest kind I know and spreads its foliage horizontally. *E. amaryllidifolia*, as the name indicates, has *Amaryllis*-like foliage. *E. bicolor*, a native of Natal, introduced about 1878, is a handsome, robust species; it obtained an Award of Merit from the Royal Horticultural Society in June, this year, and was figured in *The Gardeners' Chronicle* (Fig. 12, p. 23). W. J. P.

BULBINELLA HOOKERII.

STILL frequently called by its now superseded specific name of *Chrysobactron*, *Bulbinella Hookerii* is not too well known to the average owner of a garden devoted mainly to hardy flowers. A goodly number of years ago, as the writer recollects, the plant was a good deal in favour and was often included in collections of hardy plants. In some cases it was carefully tended, but in others it received the ordinary treatment of other hardy flowers, and had a comparatively short life. It was looked upon by some as tender, and I remember when visiting a keen plantsman's garden, seeing two specimens of this plant growing in a frame preparatory to being put out for the summer. This was unnecessary, but the fact remains that a great many losses have occurred, probably from want of understanding the conditions called for by *B. Hookerii*. It is really a bog plant, and the fare provided in the ordinary border is generally uncongenial, hence the frequency of the losses. It is worth considering by those who can give it a bog or even a moist border or a position at the base of a rock garden, into which the rainfall from the higher parts can flow and form semi-boggy conditions. It needs sunshine.

B. Hookerii is a pretty *Asphodel*-like plant, two feet or so high, more or less, and having long foliage, and spikes of yellow flowers. There appear to be two forms, at least, one answering to the above description and another which is taller and has larger spikes and individual flowers. The latter, to which no name has been given, is very scarce. Plants may be raised from seeds or increased by division. S. Arnott.

DOUBLE TULIPS.

So long ago as 1665, double Tulips were grown in England, and a few varieties are figured in books of the period. The double sorts grew in favour slowly, and even in the *Dutch Florist*, written by Nicholas Van Kampen and Son of Haarlem, and published in 1763, it is mentioned that only two varieties are listed in the firm's catalogue—*La Couronne Imperiale* and *Le Mariage de Ma Fille*. During the closing years of the eighteenth century, double Tulips became more popular, and in a Dutch catalogue of that period no fewer than seventy-five sorts are listed; this was at a time, however, when there was a singular craze for double flowers of all kinds.

Throughout its history, however, the double form of the Tulip has never attained universal popularity; trade catalogues usually contain a much abbreviated list and flowers are rarely staged at exhibitions.

In favourable seasons, double Tulips are very effective in flower beds, but during inclement weather the somewhat heavy blooms

are prone to injury; as pot plants, several of the varieties are superb, and *Murillo* and *Safrano* (syn. *Tea Rose*) may be cited as good examples. During recent years new varieties have rarely appeared.

A selection of early-flowering double Tulips should include *Couronne d'Or*, orange-yellow; *Safrano* (syn. *Tea Rose* and *Brimstone*), yellow, suffused salmon; *Murillo*, white and rose-pink; *Couronne des Roses*, deep rose and white; *Salvator Rosa*, deep rose-pink and blush; *Imperator Rubrorum*, red; *Don Carlos*, perhaps the best red; *Vuurbaak*, orange-scarlet; *Tournesol*, red and yellow; *Lac Van Haarlem*, lilac-violet; *La Candeur*, pure white, outside petals at first suffused green; and *Schoonoord*, a very beautiful pure white flower.

The later-flowering double varieties form a small class and, admittedly, not a very successful one; they flower with the earlier Cottage Tulips and are, for the most part, characterised by immense flowers and weak stems. The colours are bright and attractive; a small collection would consist of *Bleu Céleste* (syn. *Blue Flag*), with tall stems and large flowers of a good shade of pale purplish-blue; *Yellow Rose*, a tall, yellow self; *Mariage de Ma Fille*, with crimson and white stripes; *Count of Leicester*, deep yellow; and *La Belle Alliance*, white ground, feathered and striped purple. Groups of these late-flowering double Tulips usually prove attractive in the hardy flower borders, and so used, they are more satisfactory than when grown in beds. Ralph E. Arnold.

FLOWER GARDEN.

CALCEOLARIA INTEGRIFOLIA.

THE true value of this *Calceolaria* is seldom recognised, owing, no doubt, to the mistaken idea that it is only suitable for use as a greenhouse or bedding plant. This is by no means the case, as although liable to being killed in very severe winters, being a native of Chili and Peru, it will survive for quite a number of years if planted against a wall, preferably one with a north or east aspect, where it will not start into growth too early and is sheltered from the full heat of the summer sun. Under these conditions and given deep, loamy soil, it will form a bushy plant three or more feet high, producing strong, erect, branching growths, which are thickly clothed with leaves, and terminated by large clusters of small, rich, golden-yellow flowers borne well above the foliage and produced freely throughout the summer and autumn.

Soon after the introduction of this *Calceolaria* there was considerable confusion amongst the authorities regarding its correct name. It was given in both the *Bot. Mag.* and *Bot. Cabinet* as *C. rugosa*, while the *Bot. Reg.* in describing it under the name of *C. integrifolia* considered it a tender annual—a mistake due, no doubt, to inexperience of its habits. However, it is given in the *Index Kewensis* as *C. integrifolia*, under which name it is now commonly grown.

There are apparently two distinct varieties of it, namely var. *viscossima*, a sticky, hairy form with sessile leaves, and var. *angustifolia*, which is figured in the *Bot. Mag.*, t. 1,083, and described as having longer, more coarsely serrated leaves and longer flower stems. A. G. F.

HARDY FLOWER BORDER.

LARGE-LEAVED SAXIFRAGAS.

THE broad-leaved *Saxifragas* belonging to the *Megasea* section are handsome foliage plants of an evergreen character, and have a decorative effect at all seasons of the year. All are strikingly beautiful when in flower in the spring and early summer, and many of them have the additional charm of vivid autumnal colouring in their foliage. They are excellent subjects for certain positions in the rock garden, as their evergreen leaves are valuable for furnishing the garden during the winter months, while planted in large, bold groups in the wild garden or woodland they are very effective.

The cultivation of this group of plants presents no difficulties; they thrive in almost any soil and position. Propagation is readily effected by division, either in the autumn or spring, while most of the species produce seeds freely and may be increased by such means.

S. ligulata is one of the earliest to flower and is liable to injury by frost if grown in an exposed position, hence a sheltered spot should be chosen for it. It is a Himalayan plant and has a tendency to lose its leaves during the winter, but its flowers are very beautiful and freely produced in large trusses in April. The variety *speciosa* retains its foliage better, which helps to protect the flowers in their early stages of growth.

S. cordifolia is one of the most robust species; with large, handsome leaves and dense spikes of rosy-red flowers produced at the end of April. It is of great value for planting in large masses in the wild garden or woodland, where it makes a most effective display in the spring with its flowers, and again in the autumn with its brightly-coloured foliage.

S. crassifolia is closely related to *S. cordifolia*, but is not quite so robust. It bears large panicles of rosy-purple flowers in April and its somewhat smaller leaves take on a rich colour in autumn. *S. Milesii* is a Himalayan species which does not flower until the end of May. It has very large leaves and the flowers are pure white.

S. purpurascens is a beautiful plant but does not grow quite so freely as others of this group. It has richly-tinted foliage and produces graceful panicles of purple flowers in early June. *S. orbiculare* has somewhat rounded leaves, is of compact growth and bears panicles of deep red flowers. *S. Leichtlinii* is the tallest member of the group and has large crimson leaves and beautiful, rose-coloured flowers.

WINTER TREATMENT OF LAWNS.

THE extraordinary mildness of October and early November necessitated the mowing of lawns until a much later date than usual, but now that the last mowing of the season is past some thought should be given to the after treatment of the lawn.

The lawn-mower has been in regular use during this moist season, and as a consequence the surface of lawns will be tightly compressed as a result of constant mowing and rolling. It will thus be necessary to institute surface cultivation, and in the first place a thoroughly hardsweeping is of great assistance. This should be followed by vigorous cultivation by means of a sharp-toothed rake on small areas, or a mechanical, spiked roller on large areas, to effect perforation of the turf and assist aeration of the roots, leaving an ideal surface for the application of a subsequent top-dressing.

During summer, while growth is active, it is difficult to apply any other top-dressing than an artificial manure, but lawns benefit immensely from a top-dressing of more bulky material, and it is while growth is nearly dormant during the winter that such an application becomes practicable.

The precise nature of the top-dressing may be varied according to the texture of the local soil. If the lawn rests on heavy clay a substantial proportion of sharp, clean sand mixed with the compost would be advantageous, but on light, sandy soils this would be unnecessary. In either case, the compost should consist largely of decayed organic matter, such as that derived from leaves, garden refuse or farmyard manure, sufficiently decomposed to pass through a fairly fine sieve. If a concentrated fertiliser is mixed with the compost, preference should be given to one of organic source, such as finely-ground hoof and horn meal, which decomposes slowly and has a lasting effect.

It is a mistake to apply very heavy top-dressings at any one operation. To obtain the greatest benefit from these dressings it is essential that the holes and crevices in the turf made by previous cultivation should be thoroughly and evenly filled. This can only be done effectively by vigorously brushing the surface with a good broom, and very heavy dressings would make this impossible. A. P. C.

ORCHID NOTES AND GLEANINGS.

LAELIA ANCEPS.

THE sunless season experienced has not been to the liking of this useful, winter-flowering Orchid, and in many cases the plants have flower spikes in a backward condition, especially the late-flowering, white varieties; therefore it is advisable to give them every encouragement by maintaining a regular temperature and allowing them all the light possible. The coloured forms, which are always the first to expand their blooms, and which are so useful at the Christmas season, are of a more robust nature and not in such a backward condition.

The flowers open when the plants have quite finished their growth, therefore the drier atmosphere necessary to preserve the flowers is not detrimental to the health of the plants, as would be the case if growth continued during the flowering period. There is often a gummy, sticky, exudation from the apex of the spike, and this should be removed with a wet sponge, otherwise the upper bracts will stick to the flower buds and prevent them opening properly.

The long spikes render it necessary to place the specimens on the plant stage until the flowering season is over; any spikes that are near the glass should be tied down out of harm's way. The supply of water at the roots should be reduced, but the rooting material must be kept sufficiently moist to allow the proper development of the flowers. J. T. B.

SPATHOGLOTTIS.

THE genus *Spathoglottis* has not, hitherto, enjoyed a very full measure of popularity and yet it is an interesting one, and contains one or two undeniably pretty species. The species are natives of China, India, the Malay Archipelago and of some Pacific islands; they are terrestrial Orchids, and although this wide geographical distribution suggests variations of temperature under cultivation, all will thrive in an intermediate temperature, except *S. aurea*, which occurs within the equatorial zone and responds best to the warmth of the East India house. These Orchids grow well in fibre and chopped Sphagnum-moss, to which should be added a small portion of loam, some crushed brick and sharp sand; they enjoy plenty of water during the growing season and a subsequent well-defined period of rest.

Spathoglottis aurea was discovered on Mount Ophir (Malacca) by Thomas Lobb, in 1849; the leaves are large, plaited, the scape tall, and the rachis many-flowered. The flowers are yellow, the sepals streaked with orange on the back, and the lip spotted with red. *S. plicata*, a species of bold growth, has purplish flowers, and is a native of Java, whence it came in 1844. *S. Fortunei* is a smaller-growing plant with yellow flowers, suffused and spotted with red; this species is abundant in Hong Kong, and was first collected by Fortune in 1844 for the Horticultural Society of London. *S. Vieillardii* possesses ovoid pseudo-bulbs; the plaited leaves are very large and the scapes tall; the sepals and petals are white, the lip pale reddish-brown with some yellow and red spotting. This fine Orchid was introduced from the Isle of Pines in 1853, and was collected subsequently in New Caledonia.

The hybrid *S. aureo-Vieillardii* is a desirable plant, and another pretty hybrid is *S. edinensis* (*pulchra* × *Fortunei*).

Other good species are *S. Petri*, discovered by Mr. Peter Veitch in the Fiji Islands in 1876; the flower is rosy-purple and the callus of the lip yellow, spotted with red. *S. rosea* was introduced from the Philippines in 1837. The pretty *S. Colmanii aurea* is occasionally seen, as is the interesting *S. Lobbii*, from Sarawak, with bright yellow, red-spotted blossoms; the last-named plant was introduced somewhere about 1875, reputedly by Messrs. Rollisson.

The species and hybrids of *Spathoglottis* are, for the most part, summer-flowering, and the best examples I have known were grown in an intermediate temperature with abundant atmospheric moisture and moderately heavy shade during bright periods. Ralph E. Arnold.

INDOOR PLANTS.

BEGONIA VERSCHAFFELTII.

THIS interesting hybrid Begonia is the result of a cross made many years ago between *B. manicata* and *B. carolinaefolia*, and although it is a great improvement upon its parent species it is seldom met with nowadays.

Where the true plant is grown it invariably attracts attention. The large, ovate, acutely-lobed leaves are a soft olive-green colour, conspicuously marked with red veins on the upper surface; the lower surface, stems and petiole are a transparent, reddish-bronze. The whole plant is thickly covered with short, stiff, reddish-pink hairs. The flowers are produced in large cymes well above the foliage and have petals of a soft rose colour merging to white at the margins.

ALPINE GARDEN.

ARTEMISIA CAMPHORATA.

Most of the *Artemisias* or Wormwoods, are noted for the fragrance of their leaves. The odour of *A. camphorata* is very distinct, yet pleasing, and quite appreciated, even by those who knew not the plant but who have been asked to touch it and smell their fingers afterwards. This special fragrance is, I think, unique in the genus, most of whose species have a distinct aromatic odour. But *A. camphorata* has another claim upon us in its foliage, which is highly pleasing, of a silvery hue, and arranged flat-ways and deeply cut. Although from Spain, it appears quite hardy, and the writer grew it for years on an elevated piece of rock-work in poor, dry soil. *A. camphorata* is increased by cuttings, and is

FIG. 192.—LAELIO-CATTLEYA YUKON VAR. UNIQUE.
R.H.S. Award of Merit, November 15. Flowers cerise and orange-yellow.
Shown by Messrs. Sanders. (see p. 412).

B. Verschaffeltii grows about two feet six inches high, and continues to flower throughout the winter in a cool greenhouse. Apart from the daintiness of the flowers, the whole plant, when viewed with the light behind it, makes a most pleasing effect. R. K.

ERLANGEA TOMENTOSA.

THE grey foliage, tomentose stems and greyish-mauve flowers of this plant harmonise delightfully. During November and December the plants are useful for the decoration of a cool greenhouse or conservatory, and may be safely utilised for house decoration.

Cuttings, inserted in spring, offer a ready means of propagation, but during the summer months, the plants derive much benefit from a sojourn in the open air; an ordinarily good compost of loam, leaf-soil and sand will meet the requirements of *E. tomentosa* and absolutely cool treatment is requisite. The average height of first-year plants is about two feet. E. A.

quite a pretty shrublet, although its greenish flowers are not of much value. It grew eventually about eighteen inches high with the writer S. Arnott.

HYPERICUM FRAGILE.

So many *Hypericums*, or St. John's Worts, offer themselves for us to select from when adding plants to our gardens that we are liable to overlook some of the most attractive. In our selection, *H. fragile* should be borne in mind, whether we eventually decide in its favour or not, but most folks who have cultivated it will be prepared to say that it ought not to be absolutely rejected, if not actually preferred. Soon after it came into commerce some of us were disposed to place it at least on an equality with the exquisite *H. reptans*, but after experience of older and larger plants modified our views, and we are hardly prepared to accord *H. fragile* such high standing. But it is a very fine species, indeed, and where it thrives well, is a picture

with its carpet of deep green leaves, branching out in all directions and decked by comparatively large flowers, larger and of a deeper gold than those of *H. Coris* or *H. reptans*, recognised as among the elite of the smaller *St. John's Worts*. It grows only a few inches high, but forms a spreading carpet. I have had plants more than a foot across.

In cultivation I have found *H. fragile* most attractive in a moraine or on a sloping bank of the rock garden. It flowers for a long season and produces seeds, which, with cuttings, afford easy methods of increase. One thing must, however, be mentioned. This is that old plants of *H. fragile* may succumb during a hard winter, and the writer has lost plants several times from the trials of an inclement season. *H. fragile* should have a free soil with leaf-mould and sand added, and may be grown in sun or shade.

GERANIUM ARGENTEUM.

ONE of the finest passages in the late Mr. Reginald Farrer's *English Rock Garden* is that in which he pictures in vivid language the beauty of *Geranium argenteum*, which he called "one of the loveliest things in nature," as seen in the grassy lawns of Mount Baldo. The passage is too long for quotation in this short note, but the fact that it was written by such a keen and often caustic critic and lover of flowers justifies me in bringing this plant once more before readers interested in the best alpine.

Mr. Farrer tells us that the plant should have starvation fare if it is to be as fine as on its native mountain. "Specially poor and stony soil" is what he recommends to prevent *G. argenteum* from growing too strongly and losing much of its charm. Yet even those who have not observed the lesson to give the plant poor fare will wax eloquent in defence of its beauty should this be called in question. Its leaves are charming in form and are delightful with their silvery sheen, and the exquisite little wild Rose-like flowers of lovely tint combine to make it a gem among alpine gems. There is a white variety also, but I prefer the type.

There is one point in which I have found my experience differ from that of Mr. Farrer. He states that *G. argenteum* usually sows itself freely in the garden. I have never found any self-sown seedlings in my garden. A stony, poor soil in a sunny place will suit this gem best, and with full sun the owner should be rewarded with many flowers from May to August. Propagation is effected by portions of the crowns struck under glass, or by seeds.

MORISIA HYPOGAEA.

WHEN the exquisite little *Morisia hypogaea* made its reappearance in British gardens a good many years ago, it was with some surprise that folks learned that it had formerly been in cultivation but had disappeared for a considerable period. Its beauty is so great that it appears passing strange that it did not even seem to be cherished in the great botanic gardens.

That this delightful plant was figured by Sweet (*British Flower Garden*, second series, t. 290), and even in a most imperfect manner by Mrs. Loudon in her *Ladies' Flower Garden of Ornamental Perennials*, Vol. I, plate 18, and then went absolutely out of cultivation, appears somewhat of a mystery. This may, perhaps, be accounted for partly by the fact that it occasionally dies off without any evident cause, but, even with this failing, it should have been retained even when a flood of bedding plants swept away so many good border and rock garden flowers.

The plant is the only known member of the genus and bears the name of Professor Moris, who discovered it in the mountains of Sardinia, whence it was introduced in 1834. It is difficult to describe in sober prose the varied charms of the *Morisia*. It forms a low tuft of glossy leaves, resembling somewhat in form those of the Dandelion, but infinitely more beautiful. These rest on the soil, and above them, but almost sessile, the bright yellow flowers appear, which by their beauty make the plant highly attractive. These flowers appear early in summer and are produced in long succession.

In cultivation, *M. hypogaea* appears to prefer a dry, well-drained, sandy soil in a sunny

place, but I have found the plants greatly improved by good soakings of clear water during dry weather in spring and summer, keeping the water from the foliage. It may be increased by seeds, [which should be sown so soon as ripe. The seeds are buried in the ground, as in the case of the *Cyclamen*, and should be carefully searched for so soon as they are likely to be ripe. A still more reliable method of increase is by means of root cuttings. These should be cut into lengths of about an inch, inserted in sandy soil in pots under glass and just slightly covered at the apex and watered carefully. A large number of plants may thus be secured from a good specimen without injuring it in the least.

POTENTILLA TONGUEI.

A HANDSOME little alpine *Potentilla* of dwarf habit and with attractive flowers is that named *P. Tonguei*. It is one of the hybrids raised about sixty or seventy years ago, and, although frequently offered in catalogues, it is not common in private rock gardens. It has long been familiar to the writer, who first saw it more than forty years ago in a large collection of the best alpine of that time. It is of dwarf, rather trailing habit, and not more than three or four inches high. It comes into flower in June, as a rule, and lasts in flower until August comes to an end. It grows well in loam, leaf-soil and sand, and may be planted in a sunny or half-shady position not overhung by trees. *P. Tonguei* is increased by division of established plants or by cuttings. It is quite hardy, but I have seen it suffer greatly if exposed long to continued drought without occasional supplies of pure water.

THE WALNEY ISLAND CRANESBILL.

WHAT has for long been a popular rock plant, but which appears to be less plentiful than before, is *Geranium lancastriense*, the Walney Island Cranesbill, understood to be a form or hybrid of *G. sanguineum*, but quite distinct in many ways. It is a very dwarf plant, only rising a few inches above the soil, with smallish leaves and wonderfully large, flesh-pink flowers, charmingly veined. It is quite hardy, but should be grown in light soil and in a sunny position. It was found on Walney Island, on the Lancashire coast, and has been in cultivation for a goodly number of years. I believe that a now departed alpinist searched the island for varieties and found some plants, but, so far as I can ascertain, these were never sent out and have probably been lost. I have been informed that some of them were very pretty. *G. lancastriense* is easily increased by division, and I have seen self-sown seedlings in my garden, and these kept true to the parent, all but one, which may, however, have been a hybrid between *G. lancastriense* and one of several other hardy Cranesbills in my garden. *S. Arnott*.

WALL GARDENS.

THE clothing of a wall with attractive plants is a fascinating enterprise fraught with much interest, but its success depends on many factors. The furnishing of an existing wall is a much more difficult problem than that of planting a wall about to be built. Moreover, the purpose of the structure, whether it serves as a retaining wall with an earth slope behind providing it plentifully with moisture, or whether it is merely a dry buttress unable to collect moisture except from rainfall or atmospheric conditions, must influence the planter in the choice of plants.

That even the dry buttress wall is capable of sustaining some plant life is often demonstrated by Nature. It is no uncommon thing, for example, to see a colony of our native *Linaria cymbalaria* growing freely on the side of a brick or stone wall where one would imagine none of the finer plants could exist, yet it is obvious that the material of which the wall is built must retain sufficient moisture to enable the plant to draw its sustenance from it. When planting such a wall, however, much may be done to assist the plants in establishing themselves by making holes in the material and filling

them with rich compost containing plenty of humus.

For such walls no plants surpass the *Sempervivums*, but once they are established many other plants succeed to a remarkable degree, and it is quite possible to attain success with many of the species of *Dianthus*, *Antirrhinums*, *Artemisias*, *Achilleas*, *Aethionemas*, *Cheiranthus*, *Onosmas* and *Hieraciums*. The plants used for the purpose should be young and small. Autumn planting is preferable to spring planting, as the plants have a chance of establishing themselves before the dry conditions of summer arrive. Where difficulties arise in establishing young plants it is sometimes possible to begin by pressing portions of earth containing seeds into crevices in the wall.

Furnishing a retaining wall—with a bank of moist earth behind it—is a much less difficult problem, and makes possible the use of a far wider range of plants, but here also success is much more certain if building and planting are carried on together, for it is important that the roots of the plants are laid well back to give them access to the moisture behind—an almost impossible task when the wall is already built.

Many plants may be used with good effect for clothing such walls, some of which seem to do better in this position than in any other. The *Acaenas*, *Aubrietias*, *Phlox subulata* and its many varieties, *Androsace lanuginosa*, *Dryas octopetala*, *Fragaria lucida*, *Gypsophila prostrata*, *Lithospermum prostratum*, several of the *Polygonums*, the creeping *Thymes* and the *Helianthemums*, are excellent subjects for draping the wall with curtains of foliage and flowers. Some of the *Saxifragas*, such as *S. sancta* and *S. apiculata*, make fine cushions, while in certain positions where conditions are not too dry, even those of the mossy kinds thrive. *Acantholimonas*, *Erodiums* and *Silenes* succeed and make excellent clumps, while such old favourites as *Arabis albida*, *Alyssum saxatile*, *Iberis gibraltarica*, *I. sempervirens*, *Cerastium tomentosum*, *Nepeta Mussinii* and *Santolina incana* grow with remarkable freedom on a wall and cover large areas in a comparatively short time. *W. A.*

TREES AND SHRUBS.

BERRY-BEARING TREES AND SHRUBS.

WHEN planting schemes are being arranged the merits of berry-bearing plants should not be overlooked as they add considerably to the brightness of the garden during autumn and winter. The Natural Order *Rosaceae* alone includes many species and varieties bearing brilliantly-coloured fruits. Ornamental Crabs are valuable, not only for their brilliantly-coloured fruits, but the fruits are useful for jelly; the best of these are John Downie, The Dartmouth, Victoria and the Siberian Crab (*Pyrus baccata*), which is also very beautiful when in flower and makes a fine, large tree. *Pyrus Aucuparia*, the Mountain Ash, is beautiful in flower and fruit; and the new *Pyrus Vilmorinii*, with rosy-pink fruits, should not be overlooked. *Pyrus toringoides*, its slender, drooping branches wreathed with small, scarlet fruits, is also very beautiful.

Euonymus europaeus, the Spindle Tree, one of the most attractive of our native shrubs or small trees, is very much overlooked by planters, but the pale scarlet fruits which show the orange-coloured seeds, are very beautiful, while the brilliantly coloured foliage during the autumn is an added attraction. *Hippophae rhamnoides*, with its silvery-grey foliage and bright orange-red fruits during autumn and early winter is a very charming shrub, but a male plant must be planted with a group of females, as male and female flowers are borne on separate plants.

Cotoneasters include numerous fine subjects, a few of the best being *C. Simonsii*, *C. humifusa*, *C. microphylla*, *C. frigida*, *C. Franchetii*, *C. horizontalis* and *C. buxifolia*; in the case of the last-named, the birds do not touch the fruits, these remaining on the plant until the following spring. The *Crataegus* family includes some fine subjects for garden

decoration, notably *C. Crus-galli*, *C. Carrieri* and *C. coccinea*. *Pyracantha coccinea* var. *Lalandei* is unrivalled for covering walls, or as bushes in the open; unfortunately, the birds are very fond of the fruits, and quickly take toll of them, but seem to have no fancy for the fruits of *P. crenulata* var. *yunnanensis*, which produces small, dull-red berries in wonderful profusion, and makes a fine wall covering. *P. angustifolia* has yellow fruits, but requires the shelter of a wall as it is not over hardy.

Barberries are a host in themselves and our native Barberry is very beautiful when in fruit, while the newer Chinese species and garden varieties provide some fine subjects, some of the best being *Berberis Wilsonae*, *B. verruculosa*, *B. subcaulialata*, *B. Prattii*, *B. brevipaniculata* and *B. polyantha*. *Viburnum Opulus* is also fine and grows well by the water-side. *Symphoricarpos occidentalis* and *S. racemosus* var. *laevigata* produce their fruits in great profusion. There are many more plants worth planting for their fruits alone, but the short list given will serve to indicate the wealth of available material. *J. Coult.*

its introduction by Mr. E. H. Wilson in 1904. Although Mr. A. E. Pratt originally discovered *B. polyantha* in Szechuan in 1899, it was left to Wilson to send seeds home five years later, to be followed by a further consignment in 1908. The flowers of this popular deciduous species are produced in June, are yellow, and are borne in long panicles drooping with the weight of from twenty to one hundred blossoms. The fruit is salmon-red in colour. *B. polyantha* is also valuable for its autumn colouring.

However, the object of this note is to emphasise the variable characteristics of the plant. When raised from seeds great variation will be found in the fruiting capabilities, size of the flower panicles, and size and colour of the fruits. Although the type should grow from six feet to eight feet high, many seedlings are of considerably less stature, with thin, weakly growths instead of the long, stout, arching stems usually associated with the plant. If *B. polyantha* is to maintain its high place in the list of desirable garden shrubs it is necessary to practice a rigorous selection of seedlings, and thereafter propagate by vegetative means. Heeled cut-

ABUTILON MEGAPOTAMICUM.

THIS remarkable shrub, a native of Brazil, and also known as *A. vexillarium*, has attracted more attention than almost any other in my garden during the last five years. There are few subjects which bloom with such extraordinary freedom as it does, for, commencing in spring, it does not cease to produce an unbroken succession of blooms until the first frosts of autumn. The flowers, moreover, are extremely showy, being a vivid yellow, set off with a large and inflated blood-red calyx, and these gorgeous objects swing like Chinese lanterns at the tips of slender stalks. The specimen here is the variegated variety, the ovate leaves being tessellated with bright yellow. This may help to explain the fact that although this shrub has been in the same position at the foot of a west wall for a good many years, growth is so slow that it is still not more than four feet in height. However, it flowers with the utmost profusion, and it is so hardy that frosts rarely affect. *A. T. J., Ro Wen, Conway, N. Wales.*

FIG. 193.—ACACIA CUNNINGHAMII.

R.H.S. Award of Merit, November 15. Flowers canary-yellow. Shown by Lionel de Rothschild, Esq., Exbury, Southampton. (see p. 413).

DIOSPYROS KAKI.

THIS deciduous Chinese shrub is a handsome foliage plant, its large, glossy leaves, frequently a foot long and three or four inches wide, being particularly attractive during the summer months. But the object of this note is to draw attention to its brilliant autumnal colouring. It is of vigorous habit and free growth; a specimen planted at the foot of a wall in these gardens in 1916 has already covered an area of two hundred square feet. For a considerable period, and lasting until mid-November, this specimen has been most effective by reason of its intense colour. The beautiful leaves are first a rich orange shade, then they turn to fiery scarlet and deep crimson, giving one the impression of a large, glowing fire in the distance. *W. Auton, Pyrford Court Gardens, Surrey.*

BERBERIS POLYANTHA.

BERBERIS polyantha has become a well-established plant in our gardens and many people have extolled the merits of this easily-grown shrub, which has held its own in face of the numerous species which have been found since

tings of firm wood strike readily if inserted towards the fall of the year in pots of sandy soil and plunged under a north wall. As with many hard-wooded plants, it is imperative that the soil be rammed hard and made firm round the base of the cutting so that the heel is in actual contact with the compost. *L. B. C.*

ITEA ILICIFOLIA.

THIS somewhat uncommon evergreen shrub thrives in a sandy, peaty soil and, during the autumn months is decidedly ornamental. The long, pendant racemes of whitish flowers are freely produced and are well displayed by the wealth of glossy-green foliage. The examples I have seen are somewhat dwarf in stature, and I am unable to write of the potential height of this shrub. *I. ilicifolia* is undoubtedly a very pretty and interesting plant for a somewhat favoured situation. The better-known *I. virginica*, a deciduous species, introduced from North America so long ago as 1744, is characterised by deep green, oblong leaves and small, white flowers freely produced during June and July. *A. C.*

HYDRANGEA QUERCIFOLIA.

A NATIVE of the South-east United States, this fine plant requires a rather sheltered position as it is liable to injury during the winter, although it is seldom killed completely. It forms a rounded bush about three feet in height in this country, though normally it rises to about six feet, producing numerous, stout, woolly growths which die back to the root-stock each winter. The leaves are borne in pairs and are broadly oval in shape, with five or seven large lobes; they are from three to eight inches in length, dark green in colour, the undersides being covered with rough down.

The flowers are carried in terminals, erect panicles up to eight inches in height, the outer sterile flowers being about an inch across, greenish-white when young, changing to a purplish tint with age; the numerous, small, fertile flowers being crowded together in the centre. It usually flowers from June to September, although this year it flowered much later than usual. *A. G. F.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C. 2.

Urgent Communications.—If sent by telegraph, these should be addressed "Gard. Chron.," Rand; or by telephone, to Gerrard, 1543.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.

Letters for Publication as well as specimens of plants for naming, should be addressed to the EDITORS, 5, Tavistock Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

CHILI AND THE ANDES.

NO. II.—ON THE WAY.

FROM the comparatively temperate delights of Bermuda we passed on to real tropics, Havana and Panama. Havana looked exquisitely beautiful as we approached it from the sea—a city of white buildings flushed by the light of dawn to a liquid, rosy-amber. But the heart of Havana, when you explore it, is less attractive. The newer, finer parts of the city recall some monster exhibition—Wembley or Earls Court—in three stages: in the making, finished (so far as such shows ever are finished), and ten years after! A medley of pretentious palaces, shanty shops, and building plots, builder-stricken with builder's messes. The older quarters have many fine and picturesque buildings and immense amount of squalour, and a general air of monstrous wickedness.

But the most distressing feature of Havana is the almost total absence of dogs. Motoring for three hours in the city and its environs, and exploring on foot for another three hours or so, I only saw three dogs. One cannot take a good view of a people content to live without dogs! We had rather hoped that by taking a car we might get out into real Cuban country and see a little of its tropical wildness, but our chauffeur had definite ideas of what we ought to see, and firmly kept us to the extensive suburbs. These are set in a strange scrub-country where countless black buzzards wheel overhead in an endless saraband of wide, sweeping circles. There are no houses in these suburbs of Havana, only palaces; large palaces, middle-sized palaces, and some quite little ones; nightmare palaces of mad millionaires, one can only suppose, each more fantastic than the last. I had always thought Le Touquet could boast some fairly bizarre architecture, but compared with the suburban palaces of Havana the wildest excesses of Le Touquet are pure Tudor!

These palace gardens were small, well-kept, and full of tropical splendour, planted, for the most part, in a dull, stilted manner, or, at any rate, the intention shown in the planning was dull. Soil, climate and the plants themselves, however, combined in a splendid exuberance to defeat the dullness of design. Where Palms and Bananas, Cannas, Hibiscus, Codiaeums, Strelitzias and such-like flourish amazingly a garden cannot be wholly dull!

Here, for the first time, I saw in its full glory what is probably the finest flowering tree in the world, the Flamboyant (*Poinciana regia*). I saw Flamboyants in Bermuda, but they had nearly finished flowering and showed only a stray splash of blossom here and there as a hint of what they might do when really trying. Yet, even thus, I thought the Flamboyant, whatever it might be as a flowering subject, the finest foliage tree I had ever seen. Superficially it has the appearance of a large, spreading Acacia, with pinnate leaves larger than any Mimosa, of an indescribably rich and beautiful velvet-green. Apart from beauty of form, the foliage has a quality of tone and texture which puts it in a class by itself, and "Flamboyant" it is aptly named. Its flowering suggests the flowering of a Horse Chestnut, the flambeaux of blossom being borne in the same profusion all over the tree's surface. But the

individual flowers are larger, and the inflorescence larger, looser, more widely spreading—and of a fiery cardinal-red colour.

One of the show places of Havana is the "Tropical Garden," and to this our chauffeur took us during our suburban wanderings. We approached it through the back premises of the largest brewery I have ever seen, and found that it is owned by the brewery and run as a public garden. The public are admitted free, and at various points in the grounds are neat, little, open-air bars where excellent iced laager beer is served free of charge! The gardens are well patronised. They have considerable natural advantages; bold, cliff-like outcrops of rugged rock and a placid river, with wide pools at whose margins grow great clumps of Water Hyacinth (*Eichornia crassipes*), and they were planted with a fair collection of tropical trees, Palms, Ferns and flowering plants. Unfortunately, none of the trees or plants are labelled, whilst in every part of the garden are virulent outbreaks of grottoesque "ornament," bridges, arbours, pergolas and nameless excrescences in rustic stucco and concrete. However, it is a free show, and one should not look a gift grotto in the mouth, especially if it dispenses free beer!

The last thing we did in Havana was to visit a "saloon" near the quay-side and drink glasses of iced Cocoonut milk from fresh, green Cocoonuts. Very good and refreshing it was, and vastly superior to the insipid milk one gets from ripe, imported Cocoonuts. I feel that I have given rather an unpleasing impression of Havana, but then it is only the passing impression of a passer-by who put himself in the hands of a casual taxi-driver, and so may have missed the best things. What might a Cuban see of London who did the same thing? St. Pancras Hotel, an ex-premier's residence in Russell Square, the Albert Memorial, and possibly Highgate Cemetery.

There was one good happening, however, in Havana. I met Rupert, and Rupert has joined the expedition. I met him a mile or two out of town, hurrying along in a very busy, purposeful manner, with a small, brown winkle-shell on his back. Directly my shadow fell across him he flashed into the shell and shammed dead. In less than thirty seconds he began to stir, and when I stooped to pick him up, in he went again. Rupert is the smallest thing in Hermit Crabs I have ever seen, and makes an engaging and very portable pet. He lives in a cigarette tin, takes a sea-water bath daily, but refuses to eat, though I have tried him with every delicacy from the cold buffet—except caviare—and including a dead fly. *Clarence Elliott.*

RHODODENDRONS AND LIME.

In August, 1914, at the instance of the late Sir Isaac Bayley Balfour, whose interest in the subject had been originally aroused by Mr. George Forrest and remained unabated up to the time of his death, I began an experiment in the cultivation, or, as it would be more correct to say, in the growth of Rhododendron species in the calcareous soil of my then garden on the hills of east Berkshire.

The initial stage of the experiment has already been described in *The Gardeners' Chronicle*,* and it is unnecessary to repeat it in detail. It is sufficient to record that the Rhododendrons furnished for the purpose by the Edinburgh Botanic Garden were either tiny seedlings or juvenile plants, of which the majority had no earth about their roots, and that no especial preparation was made for them. Indeed, the plants reached my hands before there had been an opportunity of preparing for them, and were placed in beds in which *Anemone japonica*, *Astilbe grandis*, *Michaelmas Daisies* and such like had been grown for cutting. The ground had been trenched some years before, and though in a kitchen garden, the place was too shady for vegetables, and so had not been cultivated in the accepted sense of the term. The soil was typical of that part of the Chiltern country—

a rather sticky, hungry loam, overlying the chalk, shallow, and with a superabundance of flints. It was not in any sense an ideal soil for such an experiment, for apart from its high chalk content, it was not mechanically in so good a condition as might have been wished. In after years it was easy to see that the experiment would have been fairer to the Rhododendrons and more conclusive to those interested in it if adequate preparation had been made for the plants; but at that time neither the full interest of the subject nor its possibilities had dawned on me, and at the back of my mind there was always a lurking suspicion—born, no doubt, of a knowledge of the traditionally calcifugal character of Rhododendrons—that in any case the experiment was foredoomed to failure.

At that period (1914), too, Sir Isaac Balfour's views on the subject had not crystallised, nor had his enthusiasm reached the stage at which it became infectious. He had previously been impressed by Mr. George Forrest's insistence on the fact that the Rhododendrons of the Yunnan Highlands (1) grow on and in limestone, often without humus about their roots, and with the latter among the crevices of the rocks; (2) by the explorer's conviction that "when the limestone country is left behind, Rhododendrons (in general) and Primroses are left too," and he did not share the opinion of those who, in face of Mr. Forrest's assurance to the contrary, held that the Rhododendrons of Yunnan grow in spite of the lime and in humus which, they argued—and still argue—must always be present in quantity sufficient to support Rhododendron life. Sir Isaac felt that the association of Rhododendrons with limestone over so huge an area presented a physiological problem of novel and immense interest, the solution of which would be found in research. Two years before, in one of his Masters Memorial Lectures,* he had indicated the lines he thought research should follow, and had thrown out tentative suggestions as to a possible change in the habit of the fungus and mycorrhiza, which, as Dr. Rayner's brilliant researches have shown, are associated with the root growth of certain Ericaceae. But he was not convinced, and as the time was not ripe for the marriage of research in the lavatory with controlled experiment in the garden, he welcomed the opportunity I was able to afford him of helping to probe the matter empirically.

To me, therefore, at the time, it was rather more a question of how long the plants would survive conditions so entirely different from those in which their wild progenitors flourish than of much else, and it was not till some years afterwards, when I realised how tenacious of life some of the Rhododendrons were, that my enthusiasm was aroused. It must be explained, too, that the experiment could hardly have been undertaken at a more unpropitious time, for while it began in the week following that in which Germany declared war, it had to be concluded in 1921, when conditions were only beginning to show signs of a return to the normal. During the seven years' interval, anything like serious cultivation or systematic attention was out of the question, and the plants had to take their chance. It was not possible to do more than irrigate the ground in dry weather with water which, incidentally, contained a high proportion of chalk (23° of hardness), and keep the beds reasonably mulched with leaf-mould to which a liberal allowance of chalk was added. It will be observed that what with the chalk in the ground, in the water, and in the leaf-mould, there was literally no escape from it for the Rhododendrons; the chalk was undoubtedly overdone, and the wonder is that any plants survived so needlessly drastic an ordeal.

After the trial had been in progress for three years I was able to report to Sir Isaac Balfour that broadly, the plants might provisionally be divided into four groups, as follows:—(1) Those to which chalk is death within a comparatively short time; (2) those which tolerate it and which, while to all appearance healthy and showing no sign of giving up, make but slow growth, possibly because they are naturally slow growers; (3) those which

* January 29, 1916, p. 65.

* Drought and Gardening. *R.H.S. Journ.* Vol. 38, p. 206 (1912).

flourish; and (4), those which, though growing apace, are poor in colour, i.e., yellow. *R. anthopogon*, as well as *R. argyrophyllum*, *R. Hunnewellianum* and *R. Wiltonii*, have places in this group.

In the first group are found the Himalayan and Japanese species, such as *R. Hodgsonii*, *R. arboreum* var. *Campbelliae*, *R. campylocarpum*, *R. camelliaeflorum*, *R. bullatum*, *R. Dalhousiae*, *R. dilatatum* and *R. Metternichii*, which Sir Isaac Balfour had included in the original consignment, and as was only to be expected, they soon died. Among the western Chinese species in the second group are *R. adenogynum*, *R. cephalanthum*, *R. calophyllum*, *R. Delavayi*, *R. insigne*, *R. moupinense* and *R. sinense*. Of the species which fall into the third group of flourishing plants, we find *R. Augustinii*, *R. Balfourianum*, *R. ciliatum*, *R. campylogynum*, *R. Davidsonianum*, *R. decorum*, *R. dicroanthum*, *R. Hanceanum*, *R. haematodes*, *R. lutescens*, *R. longesquamatum*, *R. micranthum*, *R. oreodoxa*, *R. pachytrichum*, *R. polylepis*, *R. rubiginosum*, *R. oleifolium** and *R. taliense*. It may be explained that the gradual change in the fourth group of plants cannot have been due to the roots finding their way out of the balls, because none of them had any worth mentioning to begin with; and long before the leaves began to change colour and finally to whiten, the mat of superficial roots had extended into the surrounding soil. This was proved again and again by temporarily lifting the plants.

Sir Isaac Balfour's observations on the position at the end of the third year were as follows:—"I note with interest that of those *Rhododendrons* which have so far come through successfully, many are forms belonging to the same series—thus: *Augustinii*, *Davidsonianum*, *Hanceanum*, *lutescens*, *polylepis*, *rubiginosum*, and their doing on lime does not surprise me. Of the others, your *Balfourianum* is probably not the species, as none of the plants we raised under that name here has so far proved to be correct; it is probably *neriiflorum*, and that is a species I should not have expected to be lime-loving; I should say the same of *ciliatum* and *decorum*. *Haematodes* I could quite well believe would not mind lime, and I say the same of *micranthum* and of *sino-virgatum*, which, by the way, I now know to be the real *oleifolium*. *Oreodoxa*, *pachytrichum* and *longesquamatum* I should not expect to be lime-loving.

"Of the others, the only one that surprises me in its growth is *cephalanthum*, for I should have thought it likely to be quite ready to live in lime soil. You will probably find that *ambiguum* will not object to lime, and the death of *villosum* surprises me, seeing that its near allies of the *Augustinii* series are so flourishing.

"I do not know why *irroratum* is so unhappy; for it has all the looks of a plant that would not mind lime.

"I do not yet get a clue from your experiment, although the results are suggestive, and I shall have to digest them more completely. Meanwhile, you have certainly broken the ground and must continue. As you have been testing the soil you should also test the plants—incinerate a leaf of each and see whether they all show a like boiling up on the addition of acid.

"A three years' guarantee of life in a lime soil will hardly tempt a grower in a lime district to invest largely in *Rhododendrons*, but if you could establish one for say seven years, I think it would induce many people to make a trial of *Rhododendrons* who have hitherto been shy of them on account of their lime soil . . . Much turns on the kind of limestone, and I hope soon to be able to determine definitely what Forrest's limestone is. If it be magnesian the problem takes a very different line."†

In the fifth year the position had changed

* Then called *R. sino-virgatum*.

† In May last, Mr. Forrest kindly sent me a copy of an analysis of the specimens of limestone he brought back with him from his last journey to Western China. It is as follows: "Calcium (as Ca O.) 50.92%; Magnesium (as Mg. O.) 1.02; Iron and Aluminium (as Fe₂O₃, Al₂O₃) 4.11; Carbon Dioxide 40.07; Insoluble residue (.29; Moisture (at 105°C.) 1.48; Blackened on heating indicating organic matter; trace of nitrogen detected." Mr. Forrest added that it is dark grey, magnesian limestone, hard and yet decomposing so readily that the streams and rivers of N. W. Yunnan are heavily charged with it, especially in the rainy season.

somewhat in that several species had to be transferred from the third group of flourishing plants to the fourth group of those which, though growing well, bore obvious signs of chlorosis. By that time the experiment seemed to have proceeded far enough in the case of these chlorotic species: there seemed no object in keeping them in the test bed until their leaves were as white as a sheet, and so they were moved to more comfortable surroundings. The species concerned were:—*R. adenogynum*, *R. argyrophyllum*, *R. Balfourianum*, *R. pachytrichum*, *R. moupinense*, *R. longesquamatum*, *R. lutescens*, *R. calophyllum*, *R. Delavayi*, *R. irroratum*, *R. trichocladium*, *R. cephalanthum*, *R. coombense*, *R. villosum*, *R. lacteum* of Wilson—as *galactinum* was then called—*R. Watsonii* and *R. Wiltonii*.

In this connection, I reported to Sir I Balfour (November 15, 1920) as follows:—"Now and again I have lifted the plants to investigate the root growth and have noticed what seems to be a peculiarity, in that while the superficial fibrous roots extend a considerable distance round the base of the plants, there is not so much growth below as one would expect, no ball,

the surface of the ground like a net-work. In another instance, that of *R. insigne*, which, as you know, though a small plant, produced its first flower truss in Britain last spring, the growth of late has been marked, and this is the more remarkable as the plant stood still for five years from the commencement of the trial and did not begin to move till about the end of 1919.* In order to make sure that this species had its roots into the surrounding soil, I lifted it recently and found a mass of roots well into the chalky ground all round the plant."

In 1921, when circumstances arose to interrupt the particular experiment, and the plants were moved to lime-free soil in Mr. Charles Scrase Dickins's garden at Coolhurst, near Horsham, certain species which had then been in the chalky soil for seven years seemed to have emerged satisfactorily from what was certainly a drastic trial. These were *R. Augustinii*, *R. ambiguum*, *R. campylogynum*, *R. chartophyllum*, *R. Davidsonianum*, *R. decorum*, *R. haematodes*, *R. Hanceanum*, *R. insigne*, *R. longistylum*, *R. micranthum*, *R. oleifolium*, *R. oreodoxa*, and *R. rubiginosum*. Many of these had grown from tiny seedlings to plants of sub-

FIG. 194.—RHODODENDRON CHARTOPHYLLUM, FR., VAR. PRAECOX, DIELS.

From a photograph by Mr. G. Forrest, showing this *Rhododendron* growing on pure limestone formation on the Lichiang Range, alt. 11,000-12,000 ft.

as it were, and only a rather thin mat of roots. These superficial roots are fed regularly with a mulching of leaf-mould, care being taken to see that a high proportion of chalk is mixed with the leaf-mould. In the case of *R. Augustinii*, for example, the top roots extend in a marked circle round the plants, the circle measuring as much as two feet on each side of it, or four feet in diameter, though the plants themselves are only four feet high. From what I have seen of similar plants in another part of the garden, it seems as if the development of the aerial roots is greater in poor soil than in richer, and there may be more in this than meets the eye; is it not possible that because of the poverty of the soil the plants derive their nourishment mainly from the mulching, so that there is especial development of the roots at the surface? There is no doubt about the amount of chalk that is added to the mulching, and also no doubt that by the time the mulching is broken down the roots are exposed to the action of light and air; you can see them quite plainly on

stantial, though varying size, and while in no case was their growth comparable to that of other plants growing in well-prepared, nearly lime-free soil—to all intents and purposes potting soil—that may have been due as much to the poor character of the ground as to the influence of the chalk.

No doubt it would be a mistake to draw any definite conclusions from a small, isolated experiment like this, continued over a comparatively brief period, and conducted under needlessly drastic conditions. On the other hand, an interesting point which emerges from the experiment is that of the Chinese *Rhododendrons* tested, none seemed so susceptible to lime poisoning as the Himalayan species. Further, it seems established that some Chinese species are more definitely calcifugal than others, while some are sufficiently tolerant of chalk to show no impatience of it after seven years in conditions which are almost immediately fatal to Himalayan *Rhododendrons*. Whether these

* *Gard. Chron.*, June 23, 1923, p. 351.

species would continue to tolerate chalk for another seven years is a point experiment alone can determine. The experiment will not have been altogether without value if it forms the basis of further trials undertaken under conditions less onerous to the plants and with species which are known to grow on limestone. That would eliminate a number of species which in the particular experiment only cumbered the ground, and would confine it to *Rhododendrons* from the Tali and Lichiang Ranges and the Muli mountains. In response to my request and without committing himself in any way, Mr. Forrest has been good enough to suggest that the following species may perhaps prove more lime-tolerant than others, and in that sense may be worth a trial by those interested enough to undertake it:—*R. blandulum*, *R. chartophyllum*, *R. Clementinae*, *R. fictolacteum*, *R. globigerum*, *R. lacteum*, *R. ledoides*, *R. lepidotum*, *R. microphyton*, *R. sphaeranthum*, *R. taliense* and *R. Traillianum*. If these are joined to those species which, as indicated above, survived my own experiment, they make up a goodly company of small, medium and large-growing species. To be conclusive the seedlings should be raised *ab initio* in limy soil. This seems essential, because, as research has shown, the welfare of *Rhododendrons* (among other genera) depends on the existence of a fungus in association with the root of the plant to form mycorrhiza—without the mycorrhiza the plant succumbs. Peat plants are attuned to a certain fungus, and if a plant is moved from an acid soil to one containing lime, the fungus, and consequently the mycorrhiza, ceases to function.

Research alone can tell us whether mycorrhiza play the same part in the welfare of the *Rhododendrons* of Yunnan as in those of India and America, and whether it is the case, as has been suggested, that in the species of the Yunnan limestone ranges, the fungus, in order to escape from the lime which it finds inimical to its existence, has migrated to the leaves. Some time before his death, Sir Isaac Balfour was all but convinced that this was so, and suggested that as a result of the migration, the plant obtained its nitrogen from the air through the leaves rather than from the soil through the roots. This is no doubt one of several points which research will elucidate, and then gardeners will know *why* one *Rhododendron* tolerates lime and another does not.

Meanwhile, experiment will show which Chinese species are poisoned by lime, and which are unaffected by it, and it is clearly in the interests of horticulture that such experiments should not be confined to one of the several forms in which lime is familiar to us, but should embrace chalk, oolitic limestone, dolomite and magnesian limestone. There is no lack of either in this country, nor, probably, any lack of careful gardeners on all these formations willing to try the experiment. Only the necessary plants are needed, and with interested amateurs overburdened with seedlings of Chinese *Rhododendron* species, the material for experimental plantings should be forthcoming in quantity. The matter is one in which the *Rhododendron* Association can lend invaluable aid.

One such experiment has been initiated on a small scale by Mr. F. C. Stern in his garden on Highdown Hill—a spur of the Southdowns, south of Chanctonbury, where there is no escape from the chalk. Beginning in 1923 with *R. rubiginosum*, *R. oreotrephes*, *R. cuneatum*, *R. Traillianum* and *R. Beesianum*, Mr. Stern has since added *R. oleifolium*, *R. rhanthum*, *R. chartophyllum*, *R. adenogynum*, *R. Clementinae*, and *R. Fargesii*, all of them species of the Lichiang Range. The plants came originally from Mr. White's nursery garden at Sunningdale, or from friends, and had all been grown in lime-free soil. They differed from the plants used in my experiment as they were not small seedlings, but rather older plants with balled roots.

In the case of this experiment the chalk is as much in evidence as it was in my original experiment, and except that the climate is much softer, the conditions are about as rigorous in the one case as in the other.

It is understood, too, that the authorities of the Royal Botanic Gardens at Kew are conducting a trial of *Rhododendrons* on magnesian limestone in the north of England.

The photograph of *R. chartophyllum* var. *praecox* (Fig. 194) is one of a number taken by Mr. Forrest in 1913 to illustrate the natural growth of *Rhododendrons* on the limestone rocks of Yunnan. A. Grove.

NOTICE OF BOOK.

Greenhouse Plants.

THIS is the fifth edition of Allendorff's serviceable work*, which speaks well for its popularity and usefulness. For the purpose of the present edition, the text has been entirely revised under the editorship of Herrn C. Bonstedt, the Göttingen horticultural expert, with the assistance of a number of distinguished collaborators. For the sake of those previously unacquainted with the book we may state that the main portion of the work takes the form of an encyclopedia; the subjects are in alphabetical order according to their botanical names and under each name is given the appropriate cultural treatment.

The length of the entries varies considerably, but, on the whole, there is probably an average of two or three names to a page. The book is enriched by a number of excellent photographic illustrations on art paper, which appear to be quite new and to have been taken specially for the present edition.

There are not many reliable works now to be obtained which deal with greenhouse plants only, and we can well understand that Allendorff's volume finds a steady demand. We cannot, however, avoid noticing in it certain defects, which might well be corrected in the next edition. The incidence of the illustrations, for instance, does not seem to bear any relation to the importance of the relative text. We turn to the entry headed "Cyclamen," a genus which the German growers have made peculiarly their own, and in the cultivation of which they are unsurpassed. Although the text occupies nearly seven-and-a-half pages, there is no *Cyclamen* illustration at all! Nor is this to be accounted for by the theory that *Cyclamens* are too well-known to need illustrating, for a few pages further on we find an illustration of a house full of Carnations (unnamed). The titles under the illustrations, moreover, have been carelessly applied; for instance, in the section of plants whose names begin with "L" we find a photograph of *Levkojen*, although this is not a botanical name at all, and the text-section is properly placed under "*Cheiranthus*." As no page-references are given under the illustrations, errors like these should have been avoided.

Another defect, in our opinion, is the very scanty advice given on the subject of pests and diseases, many quite common pests not being mentioned at all, and those that are mentioned being summarily dismissed with a few words on a suggested remedy, usually without any indication of the proper quantities or proportions to be used (see pp. 47, 244). A number of printing errors have slipped through into the new edition, and some have unfortunately been perpetuated in the index, such as "*Warzenkaktus*" for "*Walzenkaktus*" (p. 272). *Rhododendron* "*Nuttalii*" appears on p. 396, and *Chrysanthemum* "*Tramfield*" Orange on p. 109. Also, the printers should know that the long "S" is not used in English words, such as "Miss" and that "Prinzess" Mary is not so called. In fact, in the list of *Chrysanthemum* names, many of which are French and English, on pp. 108-110, there are numberless mistakes, and it would have been worth while for the editor to send for a few reliable catalogues by which to check them. It is a pity that a book of this kind, upon which, evidently, much time and money have been spent, should be marred by defects so easily avoided.

The volume is well printed on good paper, and has a stout, serviceable cover protected by a paper jacket. It is a little on the heavy side, and it is probable that if the next edition has to be enlarged, the publishers will find it necessary to divide the work into two volumes.

* Allendorff's *Kulturpraxis der Kalt- und Warmhauspflanzen*. Fünfte Auflage, herausgegeben von C. Bonstedt, Garteninspektor in Göttingen. Berlin, Verlagsbuchhandlung Paul Parey, Hedemannstr. 10/11. Price Rm. 19.00.

COMPENSATION FOR ALLOTMENT GARDENS.

THE subject of the right of tenants of allotment gardens to claim compensation is dealt with under the provisions of the Allotments Act of 1922. This Act applies to what are known as "Allotments" and "Allotment Gardens," the former being any piece of land of not more than two acres in extent, and cultivated as a farm or garden or partly as a garden and partly as a farm; and an allotment garden being any allotment not exceeding forty poles in extent, which is wholly or mainly cultivated by the occupier for the production of vegetable or fruit crops for the consumption of himself or his family.

With regard to allotment gardens, a tenant is entitled to compensation for certain improvements when his landlord terminates the tenancy either (1) between April 6 and September 29, or (2) by three months' notice to quit, where the land is required for building and similar purposes, or for some public works purposes, or where the land is let by a local authority and they require it for their own use.

Compensation can be claimed from the landlord for any crops growing on the land in the ordinary course of cultivation upon it as an allotment garden and also for manure which has been applied to it. Against this, however, anything which is due to the landlord from the tenant for arrears of rent or for a breach of the tenancy agreement, and any damage the tenant may have done to his allotment, must be deducted from the amount of compensation the landlord would otherwise have to pay.

If, however, the landlord terminates the tenancy between September 29 and October 11, the tenant, although he cannot claim compensation, will be entitled to remove any crops growing on the land, provided he does so within twenty-one days after the end of his tenancy.

In the case of an allotment, the tenant can claim compensation from his landlord for crops, including fruit, growing on the land in the ordinary course of its cultivation, and also for labour expended upon and manure applied to the land. Secondly, he is entitled to compensation for fruit trees and bushes which he has himself provided and planted with the written consent of the landlord, and also for drains, outhouses, pigsties, fowl-houses and other structural alterations and improvements which he has made or erected, at his own cost, and with the consent of the landlord.

As in the case of allotment gardens, the landlord can set off against this anything which is due to him from the tenant in respect of the allotment, and so reduce the amount of compensation he will have to pay.

With regard to the removal of certain improvements by the tenant, Section 4 of the Allotments Act of 1922 provides that before the termination of the tenancy, the tenant of an allotment or allotment garden may remove any fruit trees or bushes which he has provided and planted and any erection, fencing or other improvement he has put up or made at his own expense; he must, however, make good any damage he does to the property in doing this.

The question of the right of a tenant who has paid compensation to an outgoing tenant yet remains to be dealt with, and the rule here is that where the tenant of an allotment has paid compensation to an outgoing tenant for any fruit trees or bushes or other improvements, he shall have the same rights as to compensation or removal as he would have had if the fruit trees or bushes had been provided and planted by him or the other improvements had been put up by him.

Lastly, if the landlord and tenant cannot come to an agreement as to what the amount of the compensation should be, it can be settled by a valuation by a valuer appointed by a County Court Judge. In most cases, no doubt, the parties will be able to come to terms, and should always try to do so, since the valuer's expenses will have to be paid between them, and even if the valuer awards a tenant a larger sum than his landlord was prepared to agree to, this may be reduced considerably after the valuer's expenses have been deducted. H. Sharman.

MESEMBRYANTHEMUM.

(Continued from p. 409.)

12.—GLOTTIPHYLLUM, HAW.

6. *G. longipes*, N. E. Br. (Fig. 195).—Growths decumbent or prostrate. Leaves 3-3½ inches long and 6-8 lines broad, flat on the face, rounded on the back at the lower part, becoming keeled and compressed at the apex which in the larger leaf of each pair is produced shortly beyond the flat face and in side view is obtusely rounded; and this leaf is incurved,

FIG. 195.—GLOTTIPHYLLUM LONGIPES.

Pair of leaves, adapted from Salm Dyck. Flowers pedicellate.

while the other leaf of each pair is acute in side view and strongly recurved, smooth, green, shining, somewhat pellucid-dotted. Pedicel about 1½ inch long and 2 lines thick, terete. Calyx 4-lobed; lobes broadly ovate, two of them keeled. Corolla, 2-2½ inches in diameter; petals in two series, linear, obtusely pointed, entire, yellow. Stamens numerous, yellow. Stigmas 8, plumose, yellowish.

and description above quoted, which, as I have explained under *G. cruciatum*, does not represent the true *Mesembryanthemum cruciatum* of Haworth.

7. *G. Salmii*, N. E. Br. in *The Gardeners' Chronicle*, 1922, Vol. LXXI, p. 9 (Fig. 196).—Leaves unequal, the pairs more or less crossing one another so as to point four ways, the outer spreading, 2½-3½ inches long, 6-8 lines broad and about 4 lines thick at the base, gradually tapering to an acute apex, but the larger leaf of a pair is often obtuse in side view and usually incurved, while the smaller leaf is acute and recurved, flat on the face, with a slight pustule at its base, obliquely convex on the back, the larger leaf of a pair where it is produced beyond the flat face being compressed and keeled at the apex; surface smooth, glabrous, very green, with a whitish basal mark, pellucid-dotted, firmly fleshy. Flowers sessile. Calyx compressed, 4-lobed; lobes broadly ovate, obtuse, apiculate, all with submembranous edges, two of them gibbous-keeled. Corolla 2½ inches in diameter; petals in 1-2 series, cuneately linear, very obtuse and minutely denticulate at the apex, yellow. Stamens yellow. Stigmas 8, plumose yellowish.

Mesembryanthemum Salmii, Haw. *Suppl. Pl. Succ.*, p. 89 (1819) and *Rev. Pl. Succ.* p. 100; Link and Otto, *Ic. Pl. Select.*, p. 95, t. 44; Salm Dyck, *Mes.*, §7, f. 8; Berger, *Mes. und Port.*, p. 236.

South Africa: Locality and collector unknown, stated to have been raised from seed at Vienna in 1814.

Haworth (*Rev. Pl. Succ.*, p. 100) describes three forms of this plant, namely:—Var. *decussatum*, by which he means the typical *G. Salmii*, with leaves crossing one another more or less at right angles. Var. *semicruciatum*, Salm Dyck, *Obs. Bot.*, p. 12 (1820). "Leaves obliquely distichous, straight, not exactly decussate and more tongue-shaped." And var. *angustifolium*, "Leaves longer and narrower," *M. Salmii* var. *elongatum*, Salm Dyck, *Mes.* under §7, f. 8.

plants of *G. praepingue*. No mention is made of an apiculus in the descriptions nor any representation of it in the figure of *M. Salmii*, so that possibly the above mentioned varieties really belong to *G. praepingue* or to some closely allied species.

I have not seen a living plant of *G. Salmii* and have adapted Fig. 196 from the figure,

FIG. 196.—GLOTTIPHYLLUM SALMII.

Apical part of leaves, adapted from Salm-Dyck. Flowers sessile.

quoted above. In the present state of our knowledge of these plants and in view of such proofs of variation in the leaves as I am giving evidence of under *G. semicylindricum*, *G. fragrans* and *G. longum*, may it not be possible that *G. Salmii* is only a form of *G. praepingue*? The difference between them is that in the figure and description of *G. Salmii* no indication is made of the awn-like apiculus present on most of the leaves of *G. praepingue*, and the presence of a whitish basal mark on the leaves of *G. Salmii* that is absent on those of *G. praepingue*. More native material is needed to solve this problem.

8. *G. Marlothii*, Schwantes in *Zeitschr. f. Sukkul.*, Vol. II, p. 242, with Fig. (1926), (Fig. 197).—Growths more or less prostrate with age. Leaves in two ranks, spreading, straight or recurving, with the tip of one leaf of each pair upcurved or hooked edgewise, 1½-4 inches long and 8-10 lines broad at the middle, broader at the base, 4-5 lines thick, somewhat narrowing upwards to an obtuse or slightly hooked mucronate apex, flattish or faintly concave on the face, convex on the back and the larger leaf of each pair obliquely keeled at the apex, which is obtuse but often (or perhaps always) tipped with a small point or mucro at the end of the upper edge; surface smooth but under a strong lens seen to be covered with minute raised linear surface-cells transverse to the leaf, bright green, shining, pellucid-dotted and with a row of contiguous dark spots along each edge. Flowers sessile or subsessile, fragrant. Petals rather broad. Capsule stated to be 7-11-celled in the Latin description and 7-9-celled in the German, but as figured is 7-celled.

Uniondale Division: Karoo near Uniondale, Marloth 10991!

I do not possess this species, but Mr. E. Taylor, of Southborough, having obligingly lent me his plant of it for the purpose of this description, I find that it is not allied to *G. grandiflorum* and *G. fragrans* as Schwantes states, but belongs to the same group as *G. praepingue*. Mr. Schwantes (as Berger and others have done) seems to accept the names as given by Salm Dyck as being correct, and therefore constantly creates confusion, whereas one has only to look at such of his figures as I have indicated under *G. semicylindricum* and *G. latum* and its variety to see that what is evidently but one species has been given several different names. Salm Dyck's figures are excellent, but as I have repeatedly stated, are often untrustworthy as

FIG. 197.—GLOTTIPHYLLUM MARLOTHII, SCHWANTES.

Mesembryanthemum cruciatum, Salm Dyck, *Mes.*, §7, f. 7 (not §8, f. 9), Berger, *Mes. und Port.* p. 237, f. 50, copied from Salm Dyck, not of Haworth.

South Africa: Locality and collector unknown, stated to have been raised at Schoenbrunn from South African seeds.

This species is unknown to me, and I have described it and illustrated the character of its leaves (Fig. 195) from Salm Dyck's figure

Salm Dyck sent young plants of the varieties *semicruciatum* and *angustifolium* (the latter as var. *elongatum*) to Kew in 1823, where drawings were made of them in that year. These drawings represent the leaves as straight and different in appearance from those represented in Salm Dyck's figure of *M. Salmii*, and the young leaves are very distinctly represented as being tipped with an apiculus, and I strongly suspect that these figures represent

to names, and so long as writers upon this group of plants persist in accepting his names as correct without first investigating their authenticity, so long will confusion exist.

Fig. 197 is reproduced by permission of Dr. Vaupel from the figure in the *Zeitschrift f. Sukkulantenkunde*, by means of a photograph kindly sent to me by Mr. C. A. Maass. N. E. Brown.

(To be continued.)

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

See Tables and Summaries, Ante pp. 131-137).

(Concluded from p. 411.)

WALES.

GLAMORGAN.—Owing to the late spring frosts most early Apples were a failure, but late-blooming kinds, such as Bramley's Seedling, carry fair crops. Pears and Plums that escaped the frosts carried fair crops. Peaches that were protected carried crops of good fruits. Gooseberries and Currants were quite good, and Raspberries benefited by the continuous rain. Strawberries suffered from the frosts and the crop was poor, with many deformed and useless fruits. Fruit trees are particularly healthy and free from blight and other pests. The soil is loam over limestone. W. E. Wright, Tregarth Gardens, Creigiau, Near Cardiff.

—The Apple crop generally in this district is very good. The best varieties with us are James Grieve, King of the Pippins, Cox's Orange Pippin, Lane's Prince Albert, and two or three others, which are carrying very heavy crops. Cherries, both Sweet and Morello, were very good. Bush fruits cropped abundantly, especially Gooseberries. I never saw fruit trees so free from blight. C. T. Warrington, Penllergaer Gardens, Swansea.

MONTGOMERYSHIRE.—The general outlook at flowering time was very promising for all kinds of outdoor fruits, but we have only a light crop of Pears. Apples had much better conditions this year, dry weather prevailing throughout the whole of the blossoming period, consequently we have an average crop. Plums were very lightly cropped, but we had an excellent yield of Gooseberries, Currants and Raspberries, while Strawberries were up to the average. Our soil is a clayey loam. Fruit trees are keeping much cleaner this season than usual. Wm. Durrant, Brookland Hall Gardens, Welshpool.

IRELAND, N.

MEATH.—The very wintry weather in May and June did much damage in some parts of this fruit district as we lack shelter around our orchards. Most growers have poor crops, and owing to low prices for fruits, many of them are giving up fruit-growing and are using the land for cattle grazing so as to save the expense of labour. Our soil is good, but labour is a difficult problem. Michael McKeown, Julianstown, Drogheda.

TYRONE.—The sharp frosts in late April spoiled the prospects of good crops of Pears, Plums and Cherries. Plums were a total failure, Cherries not much better and Pears about half a crop. Apples are fairly good, but the storms of wind and cold wet weather have been detrimental to the development of the fruits. Strawberries looked well but needed finer weather than they experienced. All fruits were later than usual. Our soil is a heavy clay. Fred W. Walker, Sion House Gardens, Sion Mill.

WESTMEATH.—Apples flowered well and set a fine crop of fruits, but cold, frosty winds in May caused a large amount of dropping and left a very light crop. Keswick Codling, Royal Jubilee and Bramley's Seedling are our best Apples. Plums gave much the best crop of

tree fruits. Small fruits were very good, especially Raspberries. Wm. Allan, Pakenham Hall Gardens, Castlepollard.

IRELAND, N.E.

DOWN.—Although 8° of frost were registered on two consecutive nights, when the Apples were in full blossom, there are very good crops. None of the popular varieties have failed, and Bramley's Seedling is particularly fine. The dry condition of the soil and atmosphere no doubt saved a great many of the flowers. Plums and Pears were satisfactory crops. Excepting the sturdy variety Lloyd George, most Raspberries were affected by frost. Black Currants, too, resented the low temperature. Reversion in Black Currants is becoming a nuisance, and some varieties of Strawberries show deterioration and will have to be scrapped in favour of older and more vigorous sorts. T. W. Bolas, Mount Stewart Gardens, Newtownards.

IRELAND, S.

CORK.—Severe frosts at the end of April and in early May caused serious damage to fruit crop prospects. The harsh, dry winds and cold nights that occurred throughout May, and the early part of June retarded growth, consequently the season is later than usual. Heavy rains during the latter part of June, however, saved the crops of bush fruits, but not of Strawberries. Aphides and caterpillars have been scarce, particularly where the trees were sprayed with a tar-oil solution. Apple scab has not been so prevalent as in other seasons, but bullfinches have been more destructive than usual on Apples, Pears, and Plums. In spite of the indifferent season, both tree and bush fruits have yielded better crops than was expected. J. Dearnaby, 17, St. Patrick's Terrace, Magazine Road.

KILKENNY.—There was a good display of fruit blossoms but great injury was done by frosts. Apples, Pears and Plums have cropped irregularly. In one part of our gardens there are fairly heavy crops, and in other parts light ones. Bramley's Seedling Apples are a poor crop. Victoria Plums were scarce, but most other fruits cropped fairly well. Slugs spoiled our Strawberries. There was a smaller aphid attack than usual, but mildew was bad on Gooseberries. Henry Hall, Shankill Castle Gardens, Whitehall.

—Apple trees flowered very well indeed, and were full of promise, but severe frosts at the end of April and early in May destroyed most of the blossom, with the result that crops were small. Other kinds of fruits which had set their crops earlier gave average yields of good quality. Plum trees sprayed with Carbokrimp have kept marvellously free from aphid attack this season. T. E. Tomalin, Bessborough Gardens, Piltown.

IRELAND, W.

GALWAY.—The fruit crops here are well above the average, with Apples and small fruits especially good. The weather was kind during the flowering periods and no frost was registered after the end of January. The soil is a medium loam overlying limestone; we face south and have a genial climate generally. J. Chilcott, Lough Cutra Castle Gardens, Gort.

CHANNEL ISLANDS.

GUERNSEY.—The prospects of a good fruit season were very high in the early spring, but, unfortunately, a long and very severe drought commenced just when the fruits were developing, consequently large quantities of fruits dropped. Stone fruits have suffered badly as a result of the continuous heavy winds experienced this season. C. Smith and Son, Caledonia Nursery.

—For some years past, Apricots, Plums and Peaches have practically given no crop, probably because our mild winters allow the trees no winter rest; the flowers come quite a month too soon and the pollen does not ripen. The trees flower quite well enough but, in spite of netting, the

fruits do not set. The soil is variable, from almost pure sand, through silt, then gravel—but the writer does not believe the soil has changed much, if at all, during the last fifty years, for when he was young he used to gather large quantities of Plums, Peaches and Cherries, but in those years colder winters were generally experienced, which caused the trees to rest and flower much later. W. Mauger and Sons, Brookdale Nurseries.

FRUIT REGISTER.

APPLE GOLDEN PIPPIN.

THIS Apple was much esteemed in Herefordshire and the south of England a century ago, but appears now to be somewhat scarce because it cankers in cold and heavy soils. This pretty Apple has a number (over twenty) of confusing names. Some pomologists consider it to be one of the finest dessert Apples, and over one hundred years ago it was regarded as the most delicious-flavoured Apple in cultivation, so evidently the variety was thought highly of. Golden Pippin is known to have a high specific gravity and its juice is in demand for making a fine cider. Old writers state that it was raised at Parham Park, near Arundel, Sussex. The fruits are small, roundish, inclining to oblong, regularly and handsomely shaped; the skin is rich yellow, assuming a deep golden tinge when perfectly ripe, and the whole surface is strewn with russety dots. Eye, small and open; stalk, rather long, inserted in a deep cavity; flesh, yellow, firm, crisp, very juicy and sugary, with a brisk, vinous flavour.

Golden Pippin and King of the Pippins are often gathered in the same basket for market purposes and cider making. Few trees of this pretty Apple are found in a young state, therefore its existence will evidently be short. I believe that if it were worked on the Paradise stock we should rejuvenate a very useful late Apple, as the fruits keep well until April.

APPLE ENGLISH CODLIN.

THIS very old and interesting Apple may still be found growing in out-of-the-way cottage gardens. A few years ago, I was passing through the village of Hoar Witby, near Hereford, and saw a number of trees of this old Codlin, grown from slips or cuttings. The trees were small but heavily laden with fruits of a useful size. The fruits are above medium size, conical, and irregular in outline, pale yellow with a faint blush on the side exposed to the sun; stalk, short and stout and deeply inserted. The flesh is white, tender and agreeably acid in flavour.

Some years ago, I came upon some old buckets slit up on one side and embracing some branches of this Codlin, and was informed these old buckets were going to be filled with soil to enable the branch to root and make a tree. I saw this method of propagation adopted also at Swanwick, in Hampshire, on the branches of a pet Blenheim Pippin tree; if the endeavour had been successful quite a large fruiting tree would have resulted.

APPLE CORNISH GILLIFLOWER.

THE Weeping Willow Apple fruits best on the tips of the branches, therefore great care must be used when pruning this excellent dessert variety. Cornish Gilliflower was brought to notice by Sir Christopher Hawkins, who sent it to London to be shown at the Horticultural Society's meeting in 1813. It was discovered growing in a cottager's garden, near Truro, Cornwall. As it became distributed the name of July-flower was given it, this being a corruption of the more correct name of Gilliflower, which is derived from the French *Girofle*. The fruit is of medium size; eye closed; stalk long; colour dull green on the shaded side, and sprinkled with russet on the side next the sun; flesh firm, rich and of good flavour, heavily and strongly Clove-perfumed. This Apple is in season from January to April and does exceptionally well when grown as a half-standard. Pomona.

VEGETABLE GARDEN.

GROUND WORK.

THE time of year has arrived when the business of digging and trenching the vegetable quarters should be pushed forward with all possible dispatch, and if a major portion of the work can be finished before the New Year, so much the better. Where labour and time permit, it is advisable to trench or double-dig as large an area as possible. The difficulty of obtaining adequate supplies of good manure is becoming increasingly great, therefore one has to fall back more than ever on garden refuse, which, however good it is, is not so good as manure. Those who have heavy land to deal with, and where it can be trenched, may always work plenty of leaves, spent crops of all kinds, road scrapings, etc., into the bottom trench and thus greatly help to lighten the sub-soil. The modest amount of farmyard or stable manure obtainable should be used nearer the surface.

Soils which lie wet, or are very tenacious, will benefit greatly from good dressings of ground lime and wood-ash, and a liberal quantity of both may be spread on the surface so that the winter rains and snows may wash it well in. Such dressings assist in securing a fine tilth when the ground is forked over again in the spring.

All the land dealt with should have the surface left as rough as possible; the surface of heavy soils should be ridged up for the winter. Some soils are particularly difficult to break down in the spring, even after they have been allowed to remain rough on the surface all the winter. These should have a liberal dressing of road sand or half-decayed leaves.

Ground that has carried crops of Celery and Leeks will, after these crops have been cleared, only require a good forking over to make them level, as it is almost always in good condition and ideal for a crop of Potatoes, Peas, or such roots as Carrots, Beet or Parsnips.

Land intended for Cauliflowers, Broccoli, Cabbages, Brussels Sprouts and other members of the Brassica family, should be trenched or double-dug, and the heaviest soil should be selected. If it is well-worked it will always produce finer produce than light soils, and the crops will withstand drought much better. The lighter soils should be reserved for Potatoes and root crops, Lettuces, and Spinach.

For Celery and Leeks a piece of ground that has carried crops of Carrots and Beet will be suitable, as the surface is usually fairly firm and level, and the trenches may be taken out neatly. This work should, however, be deferred until the spring or, at least, until after other ground work is finished. If the work is carried out early the sides of the trenches are liable to fall in owing to the action of the weather, and they not only present an untidy appearance, but much of the work has to be done over again.

All spent crops should be wheeled to one large heap and dressed with lime. Asparagus foliage, Pea haulm and prunings from fruit and other trees should all be burnt and the ash used for mixing with heavy soils. All old potting soil should be carefully saved and kept dry during the winter, as this forms valuable material, when sifted, for filling in the holes made for producing extra good roots of Carrots, Parsnips or Beet. In some gardens where the soil is of an unkind nature the use of this material is absolutely necessary for the production of clean shapely roots.

After the tops have been cut down, the beds of Asparagus should be cleared of weeds and top-dressed with well-decayed manure, which in turn should be covered with two or three inches of soil taken from the alleys.

Weeds have been more than usually troublesome this season, and where they still persist they should be dug in as deeply as possible. *R. W. Thatcher, Carlton Park Gardens, Market Harborough.*

HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

Damage to Foliage of Fruit Trees.—Three days after the terrific gale which passed over the British Isles on October 28, I noticed that the foliage of all our fruit trees began to change colour. In one week it had turned from very green to brown and could not have looked worse had it been scorched by a painter's blow-lamp. I have never experienced anything so drastic before. The wind was not cold, as the temperature did not fall below 50°. What factor was present to cause such havoc? Such early loss of foliage will, I fear, have a detrimental effect on the buds. Forest trees shared the same fate but, naturally, their foliage was more advanced than that of fruit trees. It would be of great interest to learn the experiences of others, especially in gardens situated more inland than ours. *J. Kneller, Penrhyn Castle Gardens, Bangor, North Wales.*

Damp in Violet Frames.—During the dull months of winter, great care is necessary with Violets growing in un-heated frames, especially double varieties. A very good method I have found to absorb superfluous moisture is to smash up some dry coke, pass it through a sieve with a half-inch mesh, and spread a thin layer between the plants. Not only does this check the effects of damp, but it keeps slugs from eating the flower buds. *F. W. D.*

Lavendula Stoechas.—In *The Gardeners' Chronicle* of October 22, "R. F." at Wisley, asks for comments from those who are growing *Lavendula Stoechas*. We brought back a few plants from the south of France in the spring of 1920, and since then have never been without it. In our small "maquis" among *Cistus*, tall *Heaths*, *Myrtles*, etc., it grows fully three feet high; in more exposed places about two feet, and in both flowers well, and is always attractive. Old, weedy plants sometimes get damaged in the winter, but more from wind than frost, I believe, as seedlings spring up profusely. *A. D., Tulse Wood, Dorset.*

Helenium Wyndley.—The answer to your correspondent, S. Arnott (p. 365), regarding the above, is to be found in the fact that it was raised by Messrs. Thos. B. Grove and Son in their nurseries at Wyndley, Sutton Coldfield. The letter "H" appearing on the label when purchased should simply apply to the species. *J. Smith.*

—I think I can help Mr. S. Arnott, regarding his query (page 365) as to the origin of *Helenium Wyndley*. In 1920, I obtained from Messrs. Thomas B. Grove and Sons, Wyndley Nurseries, Sutton Coldfield, a new *Helenium* raised by them and named *Wyndley Hybrid*. This is of precisely the same type as described by Mr. Arnott, but the colour is coppery-bronze, heavily veined on a yellow ground. It is one of the very best herbaceous plants in my collection. I think there can be no doubt that Mr. Arnott's "Wyndley" originated with Messrs. Grove, who incidentally, also sent me that really fine orange *Geum* raised by them, and called *Orangeman*. *Alan Gibbs, Tanglewood, Lisbane, Glamorgan.*

Gale Damage at The Node Gardens.—The recent gale did tremendous damage at The Node Gardens, the residence of Mrs. Carl Holmes, on October 28 and 29. A large pergola, forty-two yards long, well-furnished with creepers of various descriptions, was levelled from end to end; the gale was of terrific force, as the stone columns, fifteen inches in diameter and twenty-six in number, were all laid low, and in some instances the foundations of the columns were torn from their bedding. This disaster appears to be a blessing in disguise as it has opened up the view of the mansion to much better advantage, giving it a much more imposing appearance from various aspects. I regret no photograph

was taken while the pergola was laying on the ground. No damage was done to trees or shrubs. *W. J. Penton, The Node Gardens, Welwyn, Hertfordshire.*

Hypericum patulum Forrestii.—May I be permitted to correct the printer's error in your issue of November 12, page 385, where the habitat of *Hypericum patulum* var. *Forrestii* is given as Hunnan. This variety is, I believe, confined to the Lichiang Range, Yunnan. We may frequently expect reasonable hardiness in plants introduced from this mountainous province, whereas Hunnan is at a lower elevation (generally speaking), and farther inland, with a hotter and moister climate, even though it is geographically farther north. I may also qualify my statement regarding the reduction in length of all branches with the remark that the pruning might, with advantage, be carried a step further—the whole plant being cut down to within four to six inches of the ground, thus causing it to produce fewer and stronger growths. I mention this because several growers have recently expressed disappointment with the plant when grown in sandy soil, the growth made being described as thin and bushy. In such cases herbaceous treatment may solve the problem. *L. B. C.*

Schizostylis coccinea.—Hitherto I have grown this plant in calcareous loam, in the open garden, in as dry a situation as these gardens permit, but owing to our close proximity to the river Test, and the low level of the land, the site is unavoidably damp. I have been disappointed with the results. Doubtless in many gardens where it is grown in the open near to dark-leaved evergreens, it has given an attractive display of flowers during this remarkable autumn. A few seasons ago, the effects of early frosts induced me to resort to pot culture. A portion of the stock is potted in well-drained, eight-inch pots, using loam, a moderate admixture of sand, small potsherds, charcoal, and a little bone-meal; the pots are placed on a coal-ash bottom in the open, and the plants are placed in a cool house when the spikes show colour. I divide and repot those that have remained in their pots two seasons, but those that are potted early in the spring are top-dressed with fresh soil. Being quite hardy the plants are stood outside after being gradually inured to the prevailing weather. The results achieved prove satisfactory, for even with scant attention they certainly surpass those in the open. *Frederick Gooch.*

A Late-flowering Scarlet Catch-fly.—A rather remarkable plant is now (November 17) flowering in the open border in my garden, namely, *Silene regia*. Seeds were kindly given to me by Captain Gresham, who obtained them from the Missouri Botanic Garden. These were sown last autumn in a cold house and several seedlings appeared in the spring. They were planted out in a somewhat damp border of rich loam and soon made rather gawky plants with very much the appearance of our common *Campion*. There were no signs of buds until well into October, when they appeared in the leaf axils and at the ends of shoots which by this time were about two-and-a-half feet in length. Now the buds have expanded into vivid scarlet flowers, the petals being narrow and about half-an-inch long. The calyx is slightly larger than the petals, pale green and densely glandular. The opposite leaves and the stem are also covered with slightly viscid glands, but emit no scent that I can detect. The scarlet petals are of the same curious, scintillating quality that one finds in the flowers of *Nerines*. As the petals are narrow the flower just misses being a first-rate addition to the garden, but it seems quite possible that forms with broader petals may yet appear. My plants happen to be growing near *Lobelia fulgens* var. *Huntsman*, and the colour of the flowers is almost identical. How far *Silene regia* is going to prove hardy (if indeed it is a true perennial) I dare not yet say, but its late-flowering season makes it a desirable acquisition for gardens situated in mild districts. *N. G. Hadden, West Porlock, Somerset.*

SOCIETIES.

BIRMINGHAM CHRYSANTHEMUM.

NOVEMBER 15, 16 and 17.—This Society's annual show, held in Bingley Hall, Birmingham, on the above dates, was a pronounced success. It was larger than the one held a year ago, and the quality of the exhibits generally was considered satisfactory. Single-flowered Chrysanthemums were shown in great numbers, and also large Japanese blooms. There were six entries in the class for thirty-six Japanese blooms, but Chrysanthemums exhibited on boards seem to find little favour at Birmingham, as only two exhibits were forthcoming. Of miscellaneous plants, Begonia Gloire de Lorraine was shown extensively and in excellent condition, while Cyclamens, too, were good, but Primulas and Pears were poorly represented. Table decorations were greatly admired, and vegetables were particularly well and extensively shown. The weather during the whole of the show was very mild, and the attendance satisfactory.

GROUPS.

In the class for a group of Chrysanthemums arranged as grown, with Ferns and foliage plants, on a ground space of fifteen feet by six feet, there were two entries against three last year. The first prize of £12 was again won by VISCOUNT COBBAM, Hagley Hall, Stourbridge (gr. Mr. J. H. Roberts), whose artistically arranged group included Japanese, Incurved, Decorative and Single-flowered varieties. About two dozen dwarf plants of Mrs. Algernon Davis were a great feature, being arranged along the front part of the group. They carried large, beautifully clean, silvery-pink flowers, indicative of a purer atmosphere than that of the Birmingham district. The variety Mrs. R. C. Pulling, of rich pure yellow colour, was also very good. Decorative and Single-flowered varieties were freely introduced, and the group was edged with Blanche Poitevine, a foot in height, carrying large numbers of pure snow-white flowers. The second prize went to GEORGE JACKSON, Esq., J.P., Berrow Court, Edgbaston (gr. Mr. E. A. Edney), whose handsome group consisted almost entirely of large Japanese blooms, rather stiffly arranged. The plants, however, exhibited good culture, but the group was not representative of the various sections into which the Chrysanthemum is divided. Two varieties of outstanding merit were Mrs. Geo. Monro and Majestic.

SPECIMEN PLANTS.

Colonel A. J. PARKES, Edgbaston (gr. Mr. L. T. Hochkins), was the only entrant in each of three classes for (1) six Decorative Japanese Chrysanthemums (Singles excluded); (2) Single-flowered varieties, disbudded, and (3) three Decorative varieties, disbudding allowed. Colonel PARKES well deserved each of the first awards, as each specimen—upwards of five feet in height—was well covered with flowers, especially the varieties Katrina, Black Hawk, Market Red, Sweet Auburn, Florrie King, Romance and H. W. Thorpe.

CUT BLOOMS.

In the class for a collection of Single-flowered Chrysanthemums, on a table space of ten feet, by five feet, Mr. H. WOOLMAN, Shirley, Birmingham, gained first prize with magnificent flowers of Mona (white), Bob Greenfield (purple), Mrs. Harry Woolman (orange-yellow), Mrs. W. J. Godfrey, Catriona, Alert, Mrs. H. Robertson, Sandown Radiance, Devonshire Cream and Stewart Smith. The second prize went to Mrs. GUTHRIE, Northampton (gr. Mr. P. Burr), whose bunch of Susan was of outstanding merit.

There were half-a-dozen first-rate entries in the principal cut bloom class for thirty-six Japanese blooms, in not fewer than eighteen varieties, and not more than three blooms of

any one variety. Each bloom was shown in a separate vase and each exhibit was arranged on a table of twelve feet by four feet, with a board eight inches high running down the centre; cut foliage was admissible for effect. The first prize of £15, which carried with it a Silver Shield, to be held for one year, was won by THE DOWAGER LADY ANNALY, Holdenby House, Northampton (gr. Mr. D. Cameron), who had large, heavy blooms of Queen Mary, Mrs. B. Carpenter, Yellow Majestic, Red Majestic (premier bloom in the show), Autumn Tints, Mrs. G. Monro, Princess Mary, Shirley Autocrat, Julia, General Petain, Victory and Mrs. A. Davis. Last year's winner, Colonel GRETTON, M.P., Melton Mowbray (gr. Mr. A. Graham), was a very close second; his best flowers were William Turner, Majestic, Shirley Golden, Mrs. G. Monro, Red Majestic, Julia, Cissie Brunton, Mrs. B. Carpenter and Mrs. A. Davis; third, Mr. H. H. TOMLINSON, Derby, whose flowers of Dawn of Day, Mrs. A. Brown, Gilbert Drabble, Princess Mary and Cissie Brunton were commendable.

In a class for nine vases of Japanese Chrysanthemums in three varieties there were four entries, the DOWAGER LADY ANNALY's excellent exhibit being placed first. The flowers of Majestic, Red Majestic and Julia were extraordinarily large, of good depth and intense colour. Colonel GRETTON, M.P., was again the runner-up with very good specimens of Princess Mary, Majestic and Mrs. B. Carpenter; third, Mrs. WAKEMAN NEWPORT, Bewdley (gr. Mr. W. Pummell). The next class was for twelve vases of Japanese Chrysanthemums in not fewer than nine varieties, arranged on a table six feet by three feet. There were five entries, and the first prize was gained by Mrs. GUTHRIE with a beautiful set of large, well-developed blooms, arranged over a ground-work of Asparagus and Berberis Aquifolium. A few of the best varieties in this notable lot were Shirley Golden, Mrs. B. Carpenter, Julia, Princess Mary and Mrs. Geo. Monro; second, G. L. WALLER, Esq., Finstall Park, Bromsgrove (gr. Mr. E. Avery), who had good specimens of Queen Mary, William Turner, Louisa Pockett and Mrs. R. C. Pulling; third, Colonel GRETTON, M.P. Colonel GRETTON M.P., also exhibited the winning three vases of a pink-coloured Japanese Chrysanthemum, showing Mrs. B. Carpenter; second, Mr. S. G. JENKINS, Berkswell, with Mrs. Algernon Davis; third, LADY ANNALY, with General Petain. The leading three vases of a crimson Japanese variety came from the last-named exhibitor, who had intensely coloured specimens of Mrs. George Monro; second, GEORGE JACKSON, Esq., J.P. (gr. Mr. E. A. Edney), who also showed Mrs. George Monro. LADY ANNALY excelled in the class for three vases of a white Japanese variety with large, substantial blooms of Queen Mary; Mr. A. FLETCHER, Kidderminster, was second, with Cissie Brunton, and G. L. WALLER, Esq., third, with Louise Pockett. The best of seven entries in a class for three vases of a yellow Japanese variety also came from LADY ANNALY, who showed uncommonly good flowers of Yellow Majestic; second, Mr. S. G. JENKINS, with Mrs. R. C. Pulling; third, Colonel GRETTON, with Yellow Majestic. LADY ANNALY was also to the fore in the class for three vases of any Japanese variety other than those mentioned above.

The class for six varieties of Single Chrysanthemums, six blooms of each variety, was well filled, there being seven entries. Premier honours went to Mrs. GUTHRIE, who showed beautiful flowers of Robert Collins, Molly Godfrey, Reginald Godfrey, Edith Dymond, Mrs. J. Palmer and Susan; second, Mr. H. WOOLMAN, whose Dorothy Capp, Mrs. R. Harris and Mrs. W. J. Godfrey were well-shown; third, Colonel GRETTON. The winning exhibit of six varieties of Decorative Chrysanthemums came from Mr. H. WOOLMAN, who had exquisite flowers of Romance, White Lady, Pink Thorpe, and Somerset; second, Colonel GRETTON, who showed Sunburst, Felix and Gloriosa exceedingly well; third, Mr. E. J. KEELING, Small Heath, Birmingham. Of the eight exhibits of nine blooms of a Single-flowered Chrysanthemum arranged for effect, the best was shown by Mrs. GUTHRIE; second, Colonel GRETTON; third, LADY ANNALY.

LOCAL CLASSES (OPEN).

Some remarkably fine blooms were exhibited in the classes reserved for local growers. The most successful exhibitor was Miss HARROLD, who was awarded five first prizes. The first prize in the class for twelve Japanese varieties, three blooms in a vase, was won by Mr. G. MOORMAN, Bournbrook, with Queen Mary, Princess Mary, Julia, Mrs. R. C. Pulling and William Rigby; second, Messrs. J. AND W. E. GREEN, Cradley, with large, heavy specimens of A. J. Norris, John H. Starr and Mrs. Gilbert Drabble; third, Miss HARROLD (gr. Mr. A. Jones). The best pair of vases of Japanese Chrysanthemums in two varieties, three blooms of each, came from Mr. THOMAS BLOWER, Perry Barr, who showed handsome specimens of Shirley Golden and William Turner; second, H. F. KEEP, Esq., Edgbaston (gr. Mr. T. W. Davis); third, Mr. G. MOORMAN. In the class for four vases of Incurved blooms (Japanese-Incurved excluded) in four varieties, three flowers in each vase, Miss HARROLD took the lead with charming flowers of Clara Wells, Romance, Miss Thelma Hartman and Frank Fustain; second, H. F. KEEP, Esq. Miss HARROLD was again the prize-winner in the class for two vases of Incurved Chrysanthemums (Japanese-Incurved excluded) in two varieties, three blooms in a vase, with refined flowers of Clara Wells and Miss Thelma Hartman; second, H. F. KEEP, Esq. Miss HARROLD was also placed first in the class for twelve varieties of Japanese Chrysanthemums, three blooms in a vase, open only to growers residing within five miles of Birmingham. She exhibited fresh blooms of Mrs. W. Holden, Frank A. Edwards, Queen Mary, Majestic and Mr. F. Slack. H. F. KEEP, Esq., and Councillor F. W. DANIELS were placed second and third, respectively.

The winning exhibit in the class for two vases of Japanese Chrysanthemums, three blooms of each variety in a vase, with the same conditions as in the last-named class, was shown by Mr. THOMAS BLOWER; second, H. F. KEEP, Esq.; third, J. A. RYMER, Esq., Hockley. The class for three varieties of Single Chrysanthemums, disbudded, made a good show, Mr. S. G. JENKINS, Berkswell, being first, with extra large flowers of Mrs. Harry Woolman, Catriona and Susan; second, Mr. E. J. KEELING; third, Miss HARROLD. Mr. E. J. KEELING was the only exhibitor in the class for three varieties of disbudded Decorative Chrysanthemums, and he was awarded the first prize for splendid specimens of Blanche de Poitou, Atalanta and In Memoriam. Mr. S. G. JENKINS won the first prize for six vases of Single Chrysanthemums, disbudded to one bloom on a stem. He had excellent flowers of Edith Dymond, Molly Godfrey and Mrs. W. E. Cattow; second, Mr. E. J. KEELING.

The following seven classes were provided for amateurs who do not employ a professional gardener regularly. Mr. F. W. HICKTON, Belbroughton, had the best Anemone-flowered varieties, and Mr. H. H. TOMLINSON, Derby, beat seven contestants in the class for two vases of Japanese varieties, three blooms of each. Mr. W. DETHRIDGE, Black Heath, gained leading honours in the single vase class for Decorative Chrysanthemums, and Mr. J. S. PEARSON, Erdington, was first in the class for three Japanese varieties. Mr. E. J. KEELING won first prizes for one vase each of (1) a Single white Chrysanthemum; (2) a Single yellow Chrysanthemum, and (3) a vase of any variety arranged for effect.

TABLE DECORATIONS.

The table decoration classes are always a feature at Birmingham. In the first of the two classes flowers were restricted to Chrysanthemums. The first prize was won by Sir GEORGE H. KENRICK, Edgbaston (gr. Mr. J. V. Macdonald), who had yellow and reddish-bronze Single varieties lightly arranged in silvered stands; a pretty effect was produced by the introduction of long sprays of Ceropegia. Mr. E. J. KEELING and Mrs. YATES, Warwick, were equal second. The first-named exhibitor used a pinkish Anemone variety and well-coloured sprays of Selaginella, while Mrs. YATES' table was decorated with a Single bronze

variety and beautifully coloured foliage of *Ampelopsis Veitchii*. There were twelve entries in this class.

In the next class, flowers other than *Chrysanthemums* were allowed, and all had to be shown in vases and/or bowls, or both. Mrs. YATES was first with a large, flat, central bowl of charmingly-arranged buds of *Rose Madame Butterfly*, intensely-coloured *Ampelopsis Veitchii* and *Selaginella* foliage were employed with good effect; second, Sir GEORGE H. KENRICK, who employed *Orchids* and *Single-flowered Chrysanthemums*; third, Mrs. E. REYNOLDS, Garningale, with red *Carnations*.

SPECIAL PRIZES.

Special prizes for *Chrysanthemums* were offered to allotment holders, members of allotment associations, per Mr. J. A. DULLER, as follow:—For one, vase of Japanese *Chrysanthemums*, in not fewer than three varieties, Mr. H. H. TOMLINSON, Derby, was first with very creditable blooms; second, Mr. R. J. EDWARDS. The last-named exhibitor won first prize in the class for six blooms of a Decorative variety, and in another for a vase of a disbudded *Single-flowered* variety.

Mr. H. Woolman offered prizes to amateurs (gentlemen's gardeners excluded) in the three following classes:—For nine Japanese blooms, in three vases: First, Mr. S. G. JENKINS, with beautifully fresh, good-sized flowers of *Majestic*, *Queen Mary*, *R. C. Pulling* and *Mrs. B. Carpenter*; second, Mr. W. T. HUDSON, *Selly Oak*; third, Mr. R. J. EDWARDS. Mr. H. H. TOMLINSON was first for six Japanese varieties on boards, with big, heavy flowers; second, Mr. R. J. EDWARDS; and in the class for twelve Japanese blooms in four varieties, shown in vases, open to gentlemen's gardeners, Mr. D. CAMERON gained the premier award with excellent examples of *Majestic*, *Yellow Majestic*, *Red Majestic* and *Mrs. George Monro*; second, Mr. E. AVERY; third, Mr. W. PUMMELL.

MISCELLANEOUS PLANTS.

In the class for twelve plants of *Begonia Gloire de Lorraine* there were six entries, which made quite a show in themselves. Colonel A. J. PARKES was first, with very large, pyramidal, profusely-flowered specimens; second, the EARL OF PLYMOUTH, *Hewell Grange*, *Redditch* (gr. Mr. F. Molyneux); third, EDWARD ANSELL, Esq., *Sutton Coldfield* (gr. Mr. A. Jeffs). The same three exhibitors were placed in the order named in a similar but smaller class for six plants of *Begonia Gloire de Lorraine*. The class for twelve *Cyclamens* attracted six contestants. The EARL OF PLYMOUTH gained the first prize, and his plants had beautifully marbled foliage and good-sized, strong-stemmed flowers; second, G. L. WALLER, Esq.; third, VISCOUNT COBHAM. In the class for six *Cyclamens*, G. L. WALLER, Esq., beat the EARL OF PLYMOUTH, who was closely followed by Miss HARROLD. GEORGE JACKSON, Esq., J.P., won first prizes for (1) six *Palms*, and (2) one *Tree Fern*; and Mr. T. ANDREWS, *Lichfield*, was placed first for (1) three *Palms*, and (2) one *Palm*. The best of three exhibits of six *Primula sinensis* came from G. L. WALLER, Esq., but they were very poor compared with the magnificent *Primulas* for which Birmingham was noted a quarter-of-a-century ago. The class for six *Primula obconica* made a much better show. G. L. WALLER, Esq., secured first prize; second, Colonel A. J. PARKES; third, the Rt. Hon. NEVILLE CHAMBERLAIN, M.P., *Edgbaston* (gr. Mr. P. G. Catt). The first prize for six plants suitable for table decoration was won by Sir GEORGE H. KENRICK; second, LADY ANNALY.

FRUIT.

The winning collection of British-grown fruit, occupying a table space of fourteen feet by four feet, came from the STUDLEY HORTICULTURAL COLLEGE, Warwickshire, and included handsome *Alicante*, *Gros Maroc*, *Lady Downes* and *Canon Hall Muscat Grapes*; *Apples* and *Pears* in great variety, together with *Plums* and other fruits; second, Mr. CHARLES GREGORY, *Chilwell*, whose display consisted of *Apples* and *Grapes*; third, Mr. A. FLETCHER, *Kidderminster*.

Mr. C. W. POWELL, *Wareham*, *Hereford*,

won six first prizes in the classes for single dishes of *Apples*, viz., *Allington Pippin* (beautifully coloured), *Gascogne's Scarlet* (very big), *Hambling's Seedling*, *James Grieve* (richly coloured); *King of the Pippins*, *Lane's Prince Albert*; and second prize for *Annie Elizabeth*, *Newton Wonder* and *The Queen*. Mr. H. WALLHEAD, *Leamington*, excelled in the classes for *Bismarck* and *Bramley's Seedling*. Mr. H. CARTWRIGHT, *Kidderminster*, had the best examples of *Annie Elizabeth* and *Newton Wonder*. The FOREST AND ORCHARD COMPANY, *Falfield*, took the first prizes for *Blenheim Pippin* and *Charles Ross*, while Mr. C. GREGORY showed the winning dish of *Cox's Orange Pippin*, which was very fine. STUDLEY COLLEGE had the best dishes of *Cox's Pomona* and *Peasgood's Nonesuch*, and Mr. H. G. BOIS, *Alcester*, was first for the *Rev. W. Wilks* and *The Queen*. The best dish of *Lord Derby* was sent by Mr. G. M. MORDEN, *Tamworth*, and Mr. W. P. ORRILL excelled in the class for *Warner's King*.

Mr. C. W. POWELL and THE FOREST AND ORCHARD COMPANY were placed first and second respectively in the class for three dishes of culinary *Apples*, and gained awards in the same order in another class for three dishes of dessert *Apples*.

Competition in the classes for single dishes of *Pears* was disappointing. The STUDLEY COLLEGE took first prize for *Beurré Diel* and *Doyenné du Comice*, while Mrs. GUTHRIE had the best dish of *Pitmaston Duchess*. The FOREST AND ORCHARD COMPANY sent the winning dish of any other variety not mentioned in the schedule. The variety exhibited was *Doyenné Georges Boucher*.

The best three bunches of black *Grapes* came from the STUDLEY COLLEGE, who showed nice, even-sized examples of *Alicante*; second, LADY ANNALY, also with *Alicante*; third, the EARL OF LICHFIELD, *Stafford* (gr. Mr. G. Smith). The last-named exhibitor led in the class for three bunches of white *Muscat Grapes*. F. SCARF, Esq., *Edgbaston* (gr. Mr. C. Grigsby), scored in the local class for black *Grapes* with *Alicante*, and Mr. S. G. FATHERS and Mr. C. G. COMPTON were placed first and second respectively in classes for culinary and dessert *Apples*.

VEGETABLES.

Competition in the class for six varieties of *Potatoes* brought nine excellent entries. Mrs. GUTHRIE was placed first, with beautifully clean, even tubers of *Arran Comrade*, *King Edward*, *Witch Hill*, *Chieftain*, *Catriona* and *Red King*; second, Mr. A. H. HICKMAN, *Cookley*, *Kidderminster*; third, Major HARCOURT WEBB, *Bewdley* (gr. Mr. W. Gaiger). The last-named exhibitor excelled in the classes for single dishes of *Carrots*, *Onions*, *Long Beet* and *Parsnips*. Mr. S. G. FATHERS took the lead with round *Beet* and yellow *Shallots*, while Mr. W. MAYCOCK, *King's Heath*, had the best *Celery* and red *Shallots*. Mr. HENRY MASTERS showed the winning exhibits of *Savoy*s and *Brussels Sprouts*, and Mr. E. J. KEELING was first for green *Cabbages* and *Red Cabbages*. Mr. A. H. HICKMAN sent the best *Cauliflowers*, and Mrs. P. ADAMS, *Kidderminster*, excelled with *Leeks*.

SPECIAL PRIZES FOR VEGETABLES.

Prizes were offered, per Mr. J. A. DULLER, for a collection of six kinds of vegetables. The ten entries in this class included some wonderfully fine exhibits. Mr. W. P. ORRILL, *Hinckley*, who gained the leading honour, had *Celery*, *Cauliflowers*, *Leeks*, *Onions*, *Potatoes*, and *Carrots*, all nicely displayed; second, Mr. A. HAYNES, *Hartlebury*; third, Mr. W. E. WHITCOMBE.

The best exhibit of four varieties of *Potatoes* was contributed by Mr. A. HAYNES; second, Mr. S. G. FATHERS; third, Mr. W. KEELEY, *Nuneaton*.

A great many prizes were offered through the same donor for single dishes of vegetables which were duplicates of the above single dish classes, and the prizes were divided very largely between the same set of exhibitors.

Messrs. Sutton and Sons offered prizes for nine kinds of vegetables. Mr. A. H. HICKMAN was awarded the first prize with splendid *Celery*,

Leeks, *Onions*, *Carrots*, *Beet*, *Tomatoes*, *Potatoes*, *Brussels Sprouts* and *Cauliflowers*; second, Mrs. P. A. ADAMS.

Messrs. Webb and Sons' prizes were for six kinds of vegetables, and Mr. A. H. HICKMAN again took the lead and Mrs. P. ADAMS was placed second.

Messrs. Dickson and Robinson's prizes were offered for nine bulbs of *Premier Onions*, and were won by Mr. WILLIAM ROBINSON, *Garstang*, Mr. E. J. KEELING and Mr. W. MAYCOCK, respectively.

Messrs. Clibran's prizes for eight kinds of vegetables went to Mr. S. G. FATHERS, and Mr. A. FLETCHER, *Kidderminster*.

HONORARY EXHIBITS.

Large Gold Medals were awarded to Messrs. WATERER, SONS AND CRISP, for hardy shrubs; Messrs. BAKERS', for floral designs; Mr. JOHN COCK, for *Potatoes*; Messrs. GUNN AND SONS, for hardy shrubs and cut *Roses*; KING'S ACRE NURSERIES, for fruit; Mr. H. WOOLMAN, for *Chrysanthemums*; KING'S ACRE NURSERIES, for *Chrysanthemums*; and Messrs. HEWITT AND Co., for hardy shrubs.

Small Gold Medals were awarded to Messrs. CLEMENT DOLLY AND Co., for flowers and vegetables; Messrs. BAKERS', for hardy shrubs; FOREST AND ORCHARD COMPANY, for shrubs; Messrs. W. HOPWOOD AND SONS, for fruit; Messrs. HEWITT AND Co., for floral designs; Mr. R. SCOTT, for hardy shrubs; and Messrs. J. AND W. E. GREEN, for *Chrysanthemums*.

Silver-gilt Medals were awarded to Mr. H. N. ELLISON, for fruit and flowers; FOREST AND ORCHARD COMPANY, for fruit; Messrs. J. P. HARVEY AND Co., for fruit and vegetables; Messrs. KENT AND BRYDON, for fruit and flowers; and Messrs. P. AND J. SMITH, for a rock and water garden.

Silver Medals were awarded to Mr. H. MASTERS for vegetables; Miss H. H. THOMPSON, for *Cacti*; and Mr. F. RICH, for flowering plants.

A Bronze Medal was awarded to Messrs. REAMSBOTTOM AND Co., for *Anemones*.

KINGSTON, SURBITON AND DISTRICT CHRYSANTHEMUM.

THE twentieth exhibition of this Society was held in the Surbiton Assembly Rooms, on the 9th inst., and proved a great success. The number of exhibits almost doubled those of last year, many new exhibitors having come forward; the quality of the blooms was remarkably good. The tradesmen's Challenge Cup for eighteen Japanese blooms was won by Mr. M. C. CANNON, gardener to A. C. E. HOWESON, Esq., of *Ditton Hall Manor*. This carried with it the Gold Medal of the National *Chrysanthemum Society* and the first prize. The Hodgson Challenge Cup for twelve Japanese blooms went to a new exhibitor, Mr. Manwaring, gardener to H. BECKER, Esq., *Surbiton*; this exhibit also wins an N.C.S. Silver Medal and the first prize. There was no competition for the Bond Challenge Cup and N.C.S. Silver-gilt Medal, offered for a group of *Single-flowering* varieties, so the Cup will be held for the year by Mr. Weaver, gardener to LADY JULIET DUFF, *Coombe Court*, *Kingston*, for a very fine exhibit of sixty dishes of hardy fruits.

Four groups of *Chrysanthemums* in pots were staged, and Mr. Pike, gardener to E. L. RALLI, Esq., *Woodlands Park*, *Leatherhead*, was placed first. His flowers were large and well-coloured. Mr. Bonner, gardener to G. WRIGLEY, Esq., *Gloucester Lodge*, *Kingston*, was second with plants that were well-grown and better grouped, but the flowers were not so fine; Mr. M. C. CANNON was third.

Amateurs who do not employ professional aid always show well at Kingston. Mr. C. HAWKINS of Kingston won the Cup offered by F. G. Penny, Esq., M.P., for nine Japanese blooms with some very fine flowers; the N.C.S. Certificate for the best exhibit staged by an amateur also accompanied the Cup in this class.

There were seven exhibitors in the class for three Japanese blooms, excluding white and yellow varieties, and Mr. C. MORRIS, gardener

to E. PARSONS, Esq., St. Lawrence, Thames Ditton, won the first prize in a keen competition. The N.C.S. Certificate for the best bloom in the show was awarded to Mr. M. C. CANNON for a very fine flower of Ajax. The best bloom in the amateurs' classes was Wm. Rigby, shown by Mr. E. WILDMAN, of Teddington.

In the class for three yellow Japanese blooms, Mr. Gill, gardener to C. P. BENNETT, Esq., Leigh Court, Cobham, Surrey, won the first prize.

Vegetables were well shown, and some of the exhibits from cottagers and allotment holders excelled those arranged by professional growers.

Messrs. KEITH LUXFORD AND Co. showed a non-competitive group, comprising some very fine Chrysanthemum blooms tastefully arranged with coloured foliage.

Mr. A. G. VINTEN, of Balcombe, staged some very brightly-coloured blooms in large bunches including some very fine single varieties, and Messrs. L. R. RUSSELL, LTD., Richmond, exhibited a group of berried plants, Ericas, Tree Ferns and similar plants.

LEEDS PAXTON.

WITH the closure of many private establishments and the reduction of many more in the Leeds district, gardening has fallen upon lean times. This year also there has been the additional handicap of an unfavourable and very late season. Under the circumstances, therefore, the thirty-fourth Chrysanthemum show of the Leeds Paxton Society, which was held in the Town Hall on November 11 and 12, was an exceedingly creditable one. Chrysanthemums have shared in the general lateness of the season, and the local blooms were, as a whole, lacking, to some extent, in substance and colour; indeed, they were completely eclipsed in the premier classes for twenty-four and twelve blooms by Mr. USHER's splendid stands from far-away Blandford.

Vegetables, too, were sparsely represented, and of hardy fruit there was very little. Still, entries were rather more numerous than usual, being nearly three hundred in number. Of these, rather more than two hundred were from exhibitors living in the immediate neighbourhood of the Yorkshire city.

In the open classes for cut Chrysanthemums there were four entrants for twenty-four Japanese in not less than eighteen varieties. Honours went to Sir R. BAKER (gr. Mr. A. G. Usher), Blandford, Dorset, who had a massive, bright, and level lot of such varieties as Mrs. G. Monro, Mrs. A. Davis, Mrs. W. Rigby and Freda Jones, particularly strong. The last-named variety received the verdict as being the premier bloom in the show. Messrs. BURTON AND SONS, Slaymaker Nurseries, Elland, were placed second with quite a good stand; and J. J. HUNT, Esq. (gr. Mr. T. Parkin), Grimston Court, York, third.

In the competition for twelve Japanese blooms the same exhibitors figured, and the order of awards remained the same as in the larger class.

In the local classes there was only one stand, from W. PENROSE GREEN, Esq. (gr. Mr. C. Shaw), Roundhay; and only one set of twelve blooms—from HAROLD GROVES, Esq. (gr. Mr. A. Welbourne), Wyther Lodge, Armley. The first prize was awarded in each case.

The classes for decorative combinations of Chrysanthemums brought out some tasteful and effective vases, epergnes and tables. Mention may be made especially of a charming table in which the Single Mary Richardson set up with *Asparagus deflexus* figured. This was shown by T. W. PAUL, Esq. (gr. Mr. F. Stables), and received the first prize in its class. Mr. STABLE was also first in the competition for an epergne of Chrysanthemums.

The classes for groups of Chrysanthemums, for many years a feature of the Leeds Show, brought out some groups which were good in every way. F. S. BANKS, Esq., was placed first here, and P. CARDWELL, Esq., Doyfield, Healey, Batley, second.

The class for a trade exhibit arranged for effect and not exceeding ten feet by six feet in dimensions, resulted in a curious position. The first prize was awarded to Mr. T. M. PETCH,

Highfield Nursery, Bradford, for a group of ornamental stove plants arranged with the taste and skill usually displayed by this exhibitor. The second prize fell to a group of fruits, chiefly Apples, staged by Mr. C. GREGORY, Chilwell, Notts.

Miscellaneous exhibits were comparatively few and reflected the leanness of the season. A Gold Medal was awarded to the UNIVERSITY OF LEEDS (Horticultural Section), for a display of Apples, bottled fruits, and examples of insects of special interest to growers of hardy fruits. All the Apples on this stand were from the Fruit Demonstration Centre at Osgodley, near Selby.

Mr. H. CARTER, Bardsey; Mr. HAROLD LAWDON, Lawnwood, Leeds; and Mr. T. CARTER, Headingley, Leeds, had groups of hardy evergreen shrubs and clipped trees, in which the common Box figured largely. It is interesting to note that the demand for such samples of topiary work is on the increase in the district, and that these trimmed and trained specimens find a ready sale.

LANCASTER HORTICULTURAL.

THE tenth exhibition of Chrysanthemums, held on November 9, by this Association, produced a fine display and secured a good attendance. The new Mayor (Councillor E. C. Parr), a late Secretary of the show, performed the opening ceremony, at which Chief Constable Harriss (President) presided.

Some very fine blooms were on view and a massive group from the CORPORATION PARKS (gr. Mr. J. Dearden) of Chrysanthemums, Salvias and foliage plants was a fine effort. Sir NORVAL HELME's (gr. Mr. T. Atkinson) winning group contained well-finished flowering plants, and he again won the Cup which he won outright last year and returned. Mr. F. SMITH won the Lady Storey Rose Bowl for twelve Japanese bloom, and the Alderman Jackson Cup for the most bloom points in the open classes. Mr. E. BOADLEY won outright the Snelson and Waters' Cup for three vases in the non-professional classes, while Miss BRIGHOUSE won Alderman I. J. Curwen's Cup for the most points in the fruit and vegetable classes.

In the plant classes, the chief prize-winners were Mr. F. SMITH, Sir NORVAL HELME, Mr. J. DEARDEN, Mr. I. WINDER and Mr. S. CARNEY, and they also won many awards in the cut bloom classes.

The premier bloom in the open classes was Queen Mary, shown by Mr. F. SMITH; and in the non-professional classes R. C. Pulling, shown by Mr. S. CARNEY was the leading flower. The best hand bouquet was shown by Mr. E. BOADLEY, and the best epergne by Mrs. T. CLAYTON, with Mrs. EMMOTT a good second. Major MILBURNE led for Begonias, and Sir NORVAL HELME for Primulas. Some fine fruits and vegetables were shown, the chief prize winners being Mr. W. ROBINSON, Miss BRIGHOUSE, Messrs. NASH AND SON (Taunton), Mr. J. KELSALL, Mr. W. CROSS, Mr. R. C. BRIGHOUSE, Mr. R. C. SLACK, Mr. J. JACKSON, and Mr. C. FOX.

ROYAL HORTICULTURAL.

THE following awards have been made to the undermentioned flowers by the Council of the Royal Horticultural Society after trial at Wisley.—(A) Award recommended for garden; (B) Award recommended for exhibition purposes; (C) Award recommended for cutting.

Gladioli.

AWARDS OF MERIT.

LARGE-FLOWERED VARIETIES:—*L'Immaculee*, (A, and B), sent by Messrs. W. J. UNWIN, Messrs. MORRIS and Messrs. DOBBIE AND Co.; *Imperator* (A, B, C), sent by Messrs. HEWITT AND Co.; *Vesta Tilley* (A), sent by Mr. VAN ZANTEN; *Etendard* (A), sent by Messrs. DOBBIE AND Co. and Messrs. R. H. BATH, LTD.; *Madame Mounet Sully* (B), sent by Messrs.

MAUGER AND SON; *Golden Measure* (A), sent by Messrs. W. J. UNWIN, Messrs. GRULLEMANS, Messrs. J. KELWAY AND SON, and Messrs. R. H. BATH, LTD.; *Sunspot* (A), sent by Messrs. J. KELWAY AND SON; *Sunset* (A, C), sent by Messrs. DOBBIE AND Co.; *Osalin A*, sent by Mr. C. SALBACH; *Hohenzollern* (A), sent by Messrs. DOBBIE AND Co.; *Prince of Wales* (A, B, C), sent by Messrs. DOBBIE AND Co., and Mr. VAN ZANTEN; *Phaenomen* (B, C), sent by Messrs. KONIJNENBURG AND MARK; *Nancy Hanks* (A, C), sent by Mr. C. SALBACH; *Early Sunrise* (A, B, C), sent by Mr. VAN ZANTEN, Messrs. W. J. UNWIN and Messrs. DOBBIE AND Co.; *Halley* (A, C), sent by Messrs. DOBBIE AND Co.; *Odin* (A, B, C), sent by Messrs. E. WEBB AND SONS, Messrs. R. H. BATH, LTD., and Messrs. MORRIS; *Thos. Edison* (A, B, C), sent by Messrs. R. H. BATH, LTD., Messrs. DOBBIE AND Co., Mr. PRINS, and Messrs. MORRIS; *Trudell Grotz* (B), sent by Messrs. R. H. BATH, LTD.; *Speculant* (A), sent by Mr. VAN ZANTEN; *Crimson Glow* (A, B, C), sent by Messrs. W. J. UNWIN, Messrs. R. H. BATH, LTD., and Messrs. GRULLEMANS; *Flaming Sword* (A, B, C), sent by Messrs. R. H. BATH, LTD., Mr. VAN ZANTEN and Messrs. DOBBIE AND Co.; *Brilliant* (A, B, C), sent by Messrs. DOBBIE AND Co., Mr. VAN ZANTEN and Messrs. R. H. BATH, LTD.; *Fair King* (A, B, C), sent by Messrs. R. H. BATH, LTD., and Mr. VAN ZANTEN; *Pride of Hillegom* (B), sent by Mr. VAN ZANTEN and Messrs. DOBBIE AND Co.; *Red Empress* (A, B, C), sent by Messrs. NIEUWENHUIS; *Energie* (A, B), sent by Messrs. DOBBIE AND Co., Messrs. W. J. UNWIN, Messrs. R. H. BATH, LTD., Mr. VAN ZANTEN and Messrs. MORRIS; *Heinrich Kausleiter* (A), sent by Messrs. R. H. BATH, LTD. and Mr. VAN ZANTEN; *Camillo Schneider* (A), sent by Messrs. KONIJNENBURG AND MARK and Messrs. W. PFITZER AND SON; *Byron L. Smith* (A, B, C), sent by Messrs. R. H. BATH, LTD. and Messrs. W. J. UNWIN; *Sweet Lavender* (A, C), sent by Messrs. R. H. BATH, LTD. and Mr. G. CHURCHER; *Sparkler* (A), sent by Messrs. DOBBIE AND Co.; *Baron J. Hulot* (A), sent by Messrs. MORRIS, Messrs. DOBBIE AND Co., Messrs. E. WEBB AND SONS, and Mr. VAN ZANTEN; *Royal Robe* (A), sent by Messrs. J. KELWAY AND SON; *Purple Glory* (A, B, C), sent by Messrs. W. J. UNWIN; *Cecilia* (B), sent by Mr. A. J. BLISS; *Triumph* (A, B, C), sent by Messrs. KONIJNENBURG AND MARK.

PRIMULINUS GRANDIFLORUS:—*La Lys* (A), sent by Messrs. R. H. BATH, LTD.; *Joannita de Castro* (A), sent by Messrs. R. H. BATH, LTD. and Messrs. W. PFITZER AND SON; *Sunnymede* (A), sent by Mr. G. CHURCHER; *Revue* (A, B, C), sent by Mr. G. CHURCHER; *La Consance* (A), sent by Messrs. R. H. BATH, LTD.; *Favourite (Krelage's)* (A, B, C), sent by Mr. PRINS, Messrs. R. H. BATH, LTD. and THE NETHERLANDS G. S.; *L'Yser* (A), sent by Messrs. R. H. BATH, LTD.; *Butterboy* (A, B, C), sent by Messrs. KUNDRED, Messrs. R. H. BATH, LTD. and Messrs. LOWE AND GIBSON; *Gelyce* (A, B), sent by Mr. G. CHURCHER; *Ada de Poy* (A), sent by Mr. C. SALBACH; *Ethelyn* (A, C), sent by Mr. G. CHURCHER; *Salmon Beauty* (A), sent by Mr. AMOS and Messrs. R. H. BATH, LTD.; *Rudolph Hertzog* (A), sent by Messrs. R. H. BATH, LTD.

PRIMULINUS.—*Souvenir* (A, B, C), sent by Messrs. MORRIS, Messrs. R. VEITCH AND SON, Messrs. BARRY AND SONS, Messrs. DOBBIE AND Co., Messrs. C. J. VAN TUBERGEN; Messrs. E. WEBB AND SONS, Mr. A. DAWKINS, and Messrs. R. H. BATH, LTD.; *Zanthia* (A, B, C), sent by Mr. AMOS, Messrs. VAN TUBERGEN and Messrs. R. H. BATH, LTD.; *Orange Queen* (A), sent by THE NETHERLANDS G. S., Messrs. E. WEBB AND SONS, Messrs. VAN TUBERGEN, Messrs. KONIJNENBURG AND MARK, Messrs. DOBBIE AND Co., Messrs. BARR AND SONS, Messrs. R. H. BATH, LTD., Messrs. W. PFITZER AND SON; *Bernard Kuhn* (B, C), sent by Messrs. R. H. BATH, LTD.; *Nydia*, sent by Messrs. W. J. UNWIN; *Rosandra* (syn. *Rosaura*) (A), sent by Messrs. W. J. UNWIN, Messrs. C. J. VAN TUBERGEN, Messrs. R. H. BATH, LTD., THE NETHERLANDS G. S. and Messrs. DOBBIE AND Co.; *Sphinx* (A, C), sent by Messrs. R. H. BATH, LTD., Mr. A. DAWKINS, THE NETHERLANDS G. S., Messrs. C. J. VAN TUBERGEN and Messrs.

DOBBIE AND CO.; *Athalia* (A), sent by Mr. AMOS and Messrs. R. H. BATH, LTD.; *Fire Queen* (A, B), sent by Messrs. R. VEITCH AND SON and Messrs. BARR AND SONS; *Scarlet Cardinal* (A), sent by Messrs. C. J. VAN TUBERGEN, Messrs. NIEWUENHUSEN, THE NETHERLANDS G. S., Messrs. DOBBIE AND CO. and Messrs. R. H. BATH, LTD.; *Topaz*, sent by Messrs. BARR AND SONS and Messrs. R. H. BATH, LTD.

HIGHLY COMMENDED.

LARGE-FLOWERED VARIETIES.—Painted Lady (A) sent by Messrs. J. KELWAY AND SON; La Lune (A), sent by Mr. VAN ZANTEN; A. B. Kundred (A, C), sent by Messrs. R. H. BATH, LTD.; Mrs. H. E. Bothin (A), sent by Messrs. R. H. BATH, LTD.; Princess America (A), sent by Mr. C. ELLIOTT; Venus (A, C), sent by Mr. VAN ZANTEN and Messrs. DOBBIE AND CO.; Panama (A), sent by Messrs. DOBBIE AND CO. and Mr. VAN ZANTEN; Mrs. Leon Douglas (C), sent by Messrs. W. J. UNWIN; Pink Perfection (A), sent by Messrs. W. J. UNWIN, Messrs. DOBBIE AND CO., and Messrs. MORRIS; Dr. Van Fleet (C), sent by Messrs. W. J. UNWIN and Messrs. R. H. BATH, LTD.; Elizabeth Tabor (A), early, sent by Messrs. W. J. UNWIN and Messrs. R. H. BATH, LTD.; Karl Volkert (A, C), sent by Messrs. R. H. BATH, LTD. and Messrs. W. PFITZER; Aurora (A, C), sent by Mr. VAN ZANTEN; Rose Ash (A), sent by Messrs. W. J. UNWIN, Messrs. R. H. BATH, LTD. and Messrs. HEWITT AND CO.; Cracker Jack (syn. Gipsy Queen) (A), and Gipsy Girl (A), sent by Messrs. R. H. BATH, LTD. and Messrs. DOBBIE AND CO.; the last two were considered to be alike; Herada (A), sent by Messrs. W. J. UNWIN; Plumtinte (A), sent by Mr. C. ELLIOTT; Catharina (A, C), sent by Messrs. R. H. BATH, LTD., Messrs. MORRIS, and Messrs. DOBBIE AND CO.; Faust (A), sent by Messrs. DOBBIE AND CO. and Mr. VAN ZANTEN; Paul Pfitzer (A), sent by Messrs. KONIJNENBURG AND MARK; Duchess of York (syn. Blue Bird) (A), sent by Messrs. R. H. BATH, LTD., Messrs. GRULLEMANS, Mr. VAN ZANTEN and Messrs. DOBBIE AND CO.; Restauration (A), sent by Mr. VAN ZANTEN; Splendour (A), sent by Mr. A. J. BLISS; Anna Everius (A), sent by Messrs. R. H. BATH, LTD., Messrs. W. J. UNWIN and Messrs. HEWITT AND CO.; Mrs. Dr. Hauff (A), sent by Messrs. R. H. BATH, LTD., Messrs. W. J. UNWIN and Messrs. GRULLEMANS; Czar Peter (A, C), sent by Messrs. DOBBIE AND CO., Messrs. R. H. BATH, LTD., and Mr. VAN ZANTEN; Jacoba van Beieren (B), sent by Messrs. R. H. BATH, LTD., Mr. VAN ZANTEN and Mr. PRINS; Johanna (A), sent by Mr. VAN ZANTEN.

PRIMULINUS GRANDIFLORUS:—Enchantress (A, C), sent by Messrs. KUNDRED; Myrtle (A), sent by Messrs. GRULLEMANS, Messrs. DOBBIE AND CO. and Messrs. R. H. BATH, LTD.; L'Ecaillon (A), sent by Messrs. R. H. BATH, LTD.; Ming Toy (A), sent by Messrs. KUNDRED and Mr. G. CHURCHER; Anamosa (A), sent by Messrs. R. H. BATH, LTD.; Copper Bronze (A), sent by Messrs. KUNDRED; La Vezouge (A), sent by Messrs. R. H. BATH, LTD.; Jewell (C), sent by Messrs. W. J. UNWIN; L'Orillon (A), sent by Messrs. R. H. BATH, LTD.; Arden (A), sent by Messrs. R. H. BATH, LTD.; Alice Tiplady (A), sent by Messrs. R. H. BATH, LTD., THE NETHERLANDS G. S., Mr. AMOS, Messrs. BARR AND SONS and Messrs. DOBBIE AND CO.; Midsummer Dream (A), sent by Messrs. R. H. BATH, LTD., Messrs. LOWE AND GIBSON and Messrs. KUNDRED.

PRIMULINUS.—Yolande (A, C), sent by Mr. A. J. BLISS; Sedan (A), sent by Messrs. R. H. BATH, LTD.; Marjoletti (A), sent by Messrs. GRULLEMANS; Sunrise (A), sent by Messrs. GRULLEMANS, Messrs. R. VEITCH AND SON, and Messrs. BARR AND SONS; Gold Else (A, C), sent by Messrs. R. H. BATH, LTD.; Sylvia (A, C), sent by THE NETHERLANDS G. S.; Lascelles (A, C), sent by Mr. PRINS; Altair (C), sent by Messrs. R. H. BATH, LTD., and Messrs. KUNDRED; Niobe (A), sent by Messrs. R. H. BATH, LTD., Messrs. BARR AND SONS, Messrs. C. J. VAN TUBERGEN and Messrs. DOBBIE AND CO.; Clio (A), sent by Mr. G. CHURCHER; Arlon (A), sent by Messrs. R. H. BATH, LTD.; Icarus (A), sent by Messrs. R. H. BATH, LTD. and THE NETHERLANDS G. S.

COMMENDED.

LARGE-FLOWERED:—White City (A), sent by Messrs. R. H. BATH, LTD.; Albatros (A), sent by Messrs. KONIJNENBURG AND MARK; Flora (A), sent by Messrs. R. H. BATH, LTD., and Messrs. DOBBIE AND CO.; Sir T. S. Hope-Simpson, sent by Messrs. J. KELWAY AND SON; Orangetinte (A, C), sent by Mr. C. ELLIOTT; Bleriot (A), and Dawn (A), sent by Messrs. DOBBIE AND CO., Mr. VAN ZANTEN, Messrs. W. J. UNWIN, Messrs. R. H. BATH, LTD., Messrs. GRULLEMANS and Mr. VAN ZANTEN; these two last were considered to be alike; War (A), sent by Messrs. DOBBIE AND CO.; and Carrick (A), sent by Messrs. DOBBIE AND CO.

HULL AND EAST RIDING CHRYSANTHEMUM.

THIS well-known north country Society held its twenty-seventh annual exhibition in the City Hall, Hull, on November 16 and 17.

The City Hall and its corridors were well-filled with groups of plants, chiefly Chrysanthemums, and these, together with an excellent display of vegetables, made a show of which Hull may well be proud. The various rooms of the Art Gallery were also utilised for the purpose of displaying table decorations and other classes of an artistic character, besides Chrysanthemums in vases, and fruits of a diverse character. The show was opened by the Lord Mayor of Hull, supported by a large company of the Society's friends.

There was only one competitor in the class for a group of Chrysanthemums interspersed with other flowering and foliage plants, and this excellent exhibit won first prize for Mr. ARNOLD RECKITT, Westerlands, Elongton (gr. Mr. W. P. Barnes). Several other groups to correspond with this competitive one were put up by the PARKS DEPARTMENT under the supervision of Mr. H. B. Witty, and these added materially to the attractiveness of the show.

The class for a mirror group of Chrysanthemums, miscellaneous flowers and foliage, arranged on a ground space not exceeding twelve feet square, is always a great feature of these shows. A mirror about three feet wide by seven feet high, with a shelf at the back (seven inches wide and five inches below the top) was provided in each case by the Society. First prize was won by the Rt. Hon. T. R. FERENS (gr. Mr. A. C. Storey), whose display was most artistic and of high quality. Single Chrysanthemums were used effectively, together with Begonias and highly-coloured foliage plants. Captain J. H. BROADLEY, Walton House, Brough, won second prize, and he also used Single Chrysanthemums, Begonias and dainty foliage plants. Third prize was awarded to Mr. A. D. HALL-WATT BISHOP, Burton Hall, Beverley (gr. Mr. H. Barratt).

Among three competitors in the class for twenty-four Japanese blooms, in not fewer than eighteen varieties, shown on boards, first prize was won by T. W. G. HEWITT, Esq. Weelsby Old Hall, Grimsby (gr. Mr. F. J. F. Fleming). The varieties worthy of note were Lady Talbot (2), Mrs. B. Carpenter (2), L. Brunton, Mrs. R. L. Kelly, Julia, Mrs. J. Gibson, Red Majestic (2), and Majestic (2)—one of these blooms being the best bloom in the show.—Mrs. R. C. Pulling, Mrs. A. Holden (2), Yellow Majestic Queen Mary, Thalia, Princess Mary, Belle Chinoise, Miss Dunston and His Majesty. A very creditable lot secured second prize for Mr. A. D. HALL-WATT, whose blooms of Mrs. B. Carpenter, Julia, R. C. Pulling, Norman Davis, Mrs. A. Holden and Belle Chinoise were noteworthy. Mr. J. W. BACKHOUSE, The Bar, Beverley, was awarded third prize.

The class for twelve Japanese blooms in not fewer than nine varieties, provided another good display. Here again Mr. HEWITT excelled, winning first prize with superb blooms, the better sorts being Lady Talbot (2), Majestic (2), Red Majestic (2), Princess Mary, Mrs. R. C. Pulling, Mrs. A. Holden, Mrs. B. Carpenter, Julia and Queen Mary. Mrs. ARTHUR WILSON, Tranby Croft, Hull, was awarded second prize for a grand lot of flowers, including Mrs. Algernon Davis, Frances Jolliffe, T. W. Pockett, Julia,

Prince Albert and Red Majestic. Third prize was won by Mr. HALL-WATT.

The four exhibits in the class for four vases of three Incurved blooms, in four distinct varieties, one variety in each vase, resulted in Mr. J. ARMITAGE, Clava, Harlow Oval, Harrogate (gr. Mr. R. Jones), winning first prize with Progress, Mr. P. Wiseman, Clara Wells and Advance. Smaller blooms of merit secured second prize for Mr. HALL-WATT, and, with large, unfinished blooms, Mr. J. J. SEARS, Glenrosa, New Waltham, Grimsby, was placed third.

There were only two exhibits in the class for one vase of three yellow Japanese blooms, and in this case Mr. HEWITT was again placed first, with good blooms of R. C. Pulling. With blooms of Queen Mary, Mr. HALL-WATT gained second prize. With three fair specimens of Mrs. B. Carpenter, in the class for one vase of a pink Japanese sort, Mr. HEWITT was awarded first prize, and with Nan Luxford, Mr. HALL-WATT was placed second. For a vase of three blooms of a dark or bronze Japanese variety, Mr. HEWITT won first prize with Majestic in grand form, and Mr. HALL-WATT followed.

In the class for six distinct Japanese varieties, three blooms in each vase, first prize was won by Mr. HEWITT, who was closely followed by The Rt. Hon. T. R. FERENS, Mr. HALL-WATT being placed third. For two vases of three Japanese blooms, one variety in a vase, Mr. HEWITT again led, showing Mrs. B. Carpenter and Mrs. A. Holden; Mr. HALL-WATT was awarded second prize.

An interesting class was that for nine vases of five blooms of disbudded Decorative Chrysanthemums, in nine varieties, one variety in each vase. Flowers exceeding six inches in diameter were not eligible. A good first prize set was shown by Mr. J. W. BACKHOUSE, who staged Jean Pattison, Blanche de Poitou, Ivy Gay, Durban, Cranfordia, H. W. Thorp, Sunshine, and others. The second prize was won by Mr. HALL-WATT, who had fine blooms of H. W. Thorp, In Memoriam, Sorcerer and Romance.

Good blooms were shown in the class for nine vases of disbudded Single Chrysanthemums, distinct varieties, one variety in each vase. The winner of the first prize was Mr. R. THOMPSON, Highgate, Beverley, whose best varieties were Edith Dymond, H. E. Smith, Molly Godfrey, Sandown Radiance, Robert Collins, Hilda Shoebridge, Susan, Golden Seal, and Mrs. Catlow (yellow).

Prizes in the class for a large vase of Chrysanthemums arranged for effect, with any kind of foliage, were well contested, and a well-arranged exhibit of Singles won the chief award for Mrs. EDWIN ROBSON, Sutton House, Sutton. Second prize was awarded to Mr. HALL-WATT for a rather unfinished arrangement, while a lightly arranged vase of Decorative Chrysanthemums secured third prize for Mrs. C. BILTON, Kingstree House, Cottingham.

The local classes were well filled, those for Single Chrysanthemums being noteworthy. The same remarks apply to the classes open to amateurs only, the competition in the classes for Single Chrysanthemums being well filled with excellent flowers.

Great interest centred in the class for a dessert table laid for six persons, decorated with Chrysanthemums only. The tables were placed down the whole length of one of the rooms of the Art Gallery and were a source of much interest to the visitors. The winning table was arranged by Mrs. J. CUMMING, Beverley Road, Hull, who secured the trophy given by the Rt. Hon. T. R. FERENS. This table was lightly arranged with crimson Single Chrysanthemums, fruits, [etc.] and was a very laudable effort. Second prize was well won by Mrs. EDWIN ROBSON, Sutton, with a charming arrangement of yellow Singles and beautiful fruit, and third prize went to Mrs. E. TINSLEY Sissons, Cottingham.

Baskets and epergnes were shown quite freely in their respective classes, but there was nothing of outstanding merit in any of them.

In the open class for eight distinct kinds of vegetables, a good collection won first prize for Mr. H. E. HAGUES, Cottingham; second prize was secured by Mr. F. BEARPARK, Hessle; and

third prize was awarded to Mr. S. W. HOPPER, Northfield, Cottingham. Local classes and allotment holders' classes were well contested, and produce of splendid quality generally shown.

In the open class for two bunches of white Grapes, first prize was well won by LORD HOTHAM, Dalton Hall, Beverley, and second prize by Mr. ARTHUR WILSON.

A similar class for black Grapes resulted in a keen contest, beautiful, well-coloured Gros Maroc winning first prize for LORD HOTHAM; second prize was won by Mr. HALL-WATT with Alicante, and third prize by Captain J. H. BROADLEY. Dessert and culinary Apples were shown extensively and well, high quality being generally represented.

It is quite impossible to mention more than a tithe of the many fine exhibits at Hull; it must suffice, therefore, that the show of the present season well maintained the traditions of the Hull Society.

Messrs. SUTTON AND SONS were awarded a Gold Medal for an exhibit of vegetables, comprising about 110 dishes, all of splendid quality and superbly arranged. A similar award was made to Messrs. E. P. DIXON AND SONS, LTD., for a highly attractive exhibit of Roses, Carnations, Chrysanthemums, Heaths, Cyclamens and other seasonable subjects, all displayed most effectively.

A Silver-gilt Medal was awarded to a group of new and choice Chrysanthemums staged by Messrs. KEITH LUXFORD AND CO., and a similar award went to Messrs. ARTHUR TRAIN AND SONS, who arranged a handsome group of Chrysanthemums, Palms, etc., in front of the platform of the City Hall.

Silver Medals were awarded to Messrs. D. TOYNE AND SONS, for a group of shrubs and Chrysanthemums; and Messrs. LINSLEYS AND DAUGHTEN, for a beautiful display of floral designs in Chrysanthemums.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

MR. T. R. BUTLER presided at the Monthly Meeting of this Society, held in the R.H.S. Hall, on Monday, November 14. Twelve new members were elected. The death certificates of two deceased members were received, and the sum of £83 7s. 11d., plus £40 funeral benefits, was passed for payment to their respective nominees. The sick-pay for the month on the Private side amounted to £92 7s. 2d., and on the State Section to £63 15s. 0d.; Maternity Benefits came to £14 10s. 0d., £15 8s. 9d. was paid in grants to ten members for optical treatment, and £34 15s. 0d. to six members for dental treatment; sixteen other cases were considered.

AYRSHIRE CHRYSANTHEMUM.

THE twenty-first annual show of winter-flowering plants, flowers, fruit and vegetables, promoted by the Ayr Chrysanthemum Society, was held in the Carrick Halls on the 16th inst. Compared with last year, the number of entries indicated an increase.

In the gardeners' section, Mr. ROBERT J. CLARK, Ayr, won the Pollock Cup with two well-grown specimens of Yellow Thorpe, and the same competitor was successful in three other plant classes, Mr. GEORGE MCCARTNEY, Monkton, being the runner-up on each occasion. The latter excelled in the class for an Incurved variety, and he also provided the best pot plant in the show.

Competition was keenest in the classes for cut blooms. Here Lt.-Col. CHARLES BROOK (gr. Mr. Thomas Cload), Kinmont, Annan, beat Mr. R. ALLAN, Whiting Bay, the present holder of the Land of Burns Chrysanthemum Cup, awarded to the four best vases containing three specimens each of Japanese varieties; his outstanding blooms were Majestic, Julia, Mrs. Spencer Chichester, Golden Champion, Princess Mary, Mrs. H. Wells, Mrs. R. H. Marsham, His Majesty and Mrs. B. Carpenter. He likewise excelled over Mr. ALLAN in the single vase of white, yellow and pink classes, and he

staged the best examples of new varieties introduced since 1924, the trio consisting of Autumn Tints, T. W. Pockett and Mrs. H. Wells. He suffered defeat in the crimson class at the hands of his Arran opponent, who was represented by three grand flowers of His Majesty. Mr. ALLAN also secured the first prize for twelve varieties shown on boards, and a similar honour awarded for four blooms of Incurved varieties. The vase of Mrs. Carpenter with which Mr. CLOAD won in the pink class, provided the best individual bloom in the show. It measured twenty-nine inches in circumference.

The Silver Cup for twelve blooms shown on boards in the competition confined to Ayrshire, went to JAMES WATSON, Esq. (gr. Mr. W. Chorley), Stanecastle, Irvine, while Mr. R. RAE, Wentworth, Ayr, obtained the leading awards for undisbudded and disbudded Single Chrysanthemums, two vases of Decorative sorts, and for a vase arranged for effect.

In the amateurs' section, Mr. NORMAN JAMIE, Ayr, won five of the six first prizes in pot plant classes, the remaining class for a Single variety being credited to Mr. PETER SPENCE, Ayr, who staged an outstanding plant of Raleigh. Mr. JAMES HUTCHINSON, Kilmarnock, obtained the custody of the Society's Silver Cup awarded to the best cut blooms, and Mr. J. W. Kerr's example of R. C. Pulling had the honour of being selected as the best bloom in the amateurs' classes. Although not fully developed it measured twenty-four inches in circumference.

Apart from the Apple classes, the display of fruits was small, but the vegetable classes were well-filled and the quality was superior. The winners of the two classes for collections were Mr. JOHN S. COWAN, Ayr, and Mr. GILBERT McILWRAITH, Beith.

Messrs. WILLIAM MARSHALL AND SON, Bellisle, showed an interesting collection of twenty-nine varieties of Chrysanthemums, while Messrs. AUSTIN AND McASLAN, Glasgow, were represented by a collection of Cyclamen seedlings and Carnations, which were effectively grouped. Messrs. SAMSON'S, LTD., exhibited shrubs, and the stand of Messrs. LEARMONT, HUNTER AND KING was notable for a large and varied collection of richly-coloured Apples.

Obituary.

J. C. Newsham—The sad news has reached us of the death of Mr. J. C. Newsham, Principal of the Monmouthshire Agricultural Institution at Usk. Mr. Newsham passed away on Sunday, October 30, at his residence at Rhadyr, near Usk. He was extremely popular in South Wales and in agricultural circles generally, and all who had the pleasure of his acquaintance will very deeply regret his demise at the early age of fifty-five years. He commenced his business career as a horticulturist, and spent some time at Kew and other well-known establishments before becoming a lecturer in horticultural and agricultural subjects. In 1900, he became Principal of the Hampshire Agricultural Institute at Old Basing, and fourteen years later was appointed Principal at Usk, where the Institution was then becoming established under the scheme for the administration of the William Jones Endowment. Mr. Newsham transformed the Rhadyr Farm into an establishment especially suitable for demonstrations of market gardening, dairying, poultry-keeping and live-stock, and in 1923, when the work at Usk was co-ordinated with that of the county of Monmouthshire, he was appointed County Agricultural Organiser. His enthusiasm and energy were unbounded, and in addition to his duties at Usk he was frequently called upon to act as examiner at the Harper Adams College and other institutions. He had the pen of a ready writer and is well-known as the author of numerous useful books, including *The Horticultural Notebook*; *Dairy Farming*; *Agriculture: Theoretical and Practical*; *Propagation and Pruning*; and *Agricultural Arithmetic*.

ANSWERS TO CORRESPONDENTS.

CARNATION RUST.—C. A. W. Your Carnations are attacked by rust. The plants may be sprayed with potassium sulphide, but if the disease is very severe your best plan is to burn the diseased plants and obtain a fresh stock.

FURNISHING FLOWER BEDS.—G. A. G. As such an early display is required, you will need something that can be put out in flower or just coming into flower. Bedding Pelargoniums are most useful for this purpose as they may be put out in flower. If you use scarlet varieties, you could plant the grey-foliaged *Centaurea* with them. Antirrhinums would, however, possibly suit your purpose better, as you may have plenty of variety, the intermediate type being best for bedding purposes. If seeds are sown indoors early in the year and the plants well-grown they should be ready for planting out by the end of May with well-developed buds, which should be in flower about the middle of June, and give a good display for the period you require. There is a wide range of colours to suit every taste. The dwarf Dahlias, Coltness Gem, if started early, may also be put out in flower at the end of May. Dinkie, a yellow-flowered variety, is the same in every way except colour. Verbenas, also, if started early, could be put out in flower, but for this season you would be well advised to try Antirrhinums, and at the same time grow small experimental batches of other likely plants.

GRAPES FAILING TO FINISH PROPERLY.—T. S. We believe the trouble is due to overcropping, and if the number of bunches is reduced another season, no doubt the vines will recover and the Grapes finish well.

NAMES OF FRUITS.—T. E. D. 1, Reinette Van Mons; 2, Pitmaston Pine; 3, Wyken Pippin; 4, Braddick's Nonpareil; 5, Herefordshire Pearmain; Pear Marie Louise.—*Kentish Cob*.—Golden Noble.—W. P. C. 1, Beauty of Waltham; 2, decayed; 3, Lord Lennox.—T. C. W. 1, Sandringham; 2, Cellini.—J. S. S. James Grieve.—A. E. M. 1 Benoni; 2, Dumelow's Seedling; 3, Flower of Kent; 4, Small's Admirable; 5, Yorkshire Beauty; 6, Winter Hawthornden; 7, Smart's Prince Arthur; 8, Hoary Morning; 9, Winter Strawberry; 10, Lady Sudeley.

NAMES OF PLANTS.—W. H. M. 1, a garden variety of *Naegelia*; 2, *Zebrina pendula*; 3, *Abutilon Sawitzii*; 4, *Coelogyne cristata*; 5, *Begonia metallica*; 6, *Achimene*, too shrivelled to identify species; 7, *Aechmea fulgens*; 8, *Dracaena Sanderiana*; 9, *Oplismenus Burmannii*; 10, *Elettaria Cardamomum*; 11, *Ruellia Portellae*; 12, *Clivia miniata*.

YOUNG BLACK HAMBURG VINES.—F. A. F. We are afraid your Black Hamburg Vines have been in seven-inch pots too long to be of much service for forcing next year. If you wish to try a few of them, select the strongest and best ripened canes and pot them into eleven-inch pots in January, using good turfy loam with a little lime-rubble and bone-meal added. Pot firmly, afford a little bottom heat, and if they are not forced too much they may give a few bunches of moderate sized Grapes. Your best plan would be to cut down the weak vines this winter, placing them in a little steady bottom heat in January, and when they have made about two inches of growth, shake out the roots and repot into eleven-inch or twelve-inch pots in warm compost, plunging them in a steady bottom-heat of 75°. Select the strongest shoot in each case and grow the plants in a moist atmosphere, feeding them liberally when established and growing freely.

The Development Commission. FEW reports issued under Government auspices make more interesting reading or contain more valuable information than those of the Development Commission, the seventh *Report** of which has recently been published. The Development Commission is an institution of which we may well be proud, for it acts as a financial benefactor to those organisations which are concerned in advancing knowledge or in improving rural conditions, and this work it does with discriminating liberality. The funds at the disposal of the Commission are in part derived from the original grant, in part from the monies provided by the Corn Production Repeal Act of 1921. They amounted in the year under review to upwards of £400,000. Nor was this the total of the funds available for agricultural research, for since the establishment of the Empire Marketing Board further financial assistance for agricultural and other institutes in this country, as well

as abroad, has been forthcoming. It can therefore no longer be asserted that State aid for agricultural research is stunted. Needless to say, it must take a long time before the full effects of this liberal policy are forthcoming, for research is a plant of slow growth, and not everyone who tends it is able to induce it to bear fruit. Yet, as the present *Report* shows, each year sees a steadily increasing output of new knowledge, much of it of no inconsiderable value to agriculture and horticulture. One criticism—we hope a helpful one—we should like to make with respect to the editing of the *Report*. The Introduction contains references to some of the more interesting discoveries which have been made at the various research institutions. For example, there is one to the discovery why the spores of *Stereum purpureum*—the fungus of Silver Leaf disease—will not germinate during the months of June, July and August. The reader would like to know the reason, but unless he has leisure to hunt through the 150 pages of the *Report* he will not have his desires satisfied. A little more in the Introduction in the way of outstanding discoveries and observations would make it of much greater interest to the informed, but not specialist reader. We would suggest that if it is impossible in the Introduction to refer to all the chief matters of interest, then a classified index of subjects of special importance should follow on the Introduction. Of course, the specialist knows where to look for the original papers, but there are many who take a real interest in the progress of agricultural science who have neither the leisure nor the inclination to read the highly technical language in which research workers are, perforce, constrained to describe the results of their investigations. How vast, complex and interconnected are the problems which the workers in agricultural science seek to resolve is illustrated on almost every page of the *Report*. Who, for example, would have anticipated that the effect of ionised air on the fertility of Barley would depend on the amount of available phosphates in the soil? With little phosphate the ionised air depresses fertility; with more, fertility is enhanced by ionised air! Who, again, would have guessed that in the two species of smut (*Ustilago levis* and *U. Hordei*) fungi of Oats and Barley there are apparently, as occurs, of course, in other fungi, hyphae which, though outwardly of similar form are in reality of opposite sex, and that though each kind grows if fusion of the two kinds does not occur, the fungus possesses insufficient power to work its parasitic way upon its host? Or who would have ventured to guess that the drying of soil leads to a large loss of nitrates, with a possible result that unless the nitrate is restored certain tropical soils may become sterile. Almost endless are the surprises of science, and so complex are the interrelations in Nature that the surprise is not that we know so little, but that we know so much. That that knowledge shall grow and become more and more fruitful is the high object which the Development Commissioners have at heart. Those engaged in pursuing that knowledge and those who profit by it alike must be grateful to the Commission for the strenuous and discreet way in which it is fulfilling its part.

"The Gardeners' Chronicle" Almanac for 1928.—Our Almanac for the ensuing year, giving the dates of the principal flower shows in Great Britain and of the meetings of horticultural and botanical societies, is now being prepared and will be published in an early issue

of the New Year. Secretaries of horticultural, botanical and other societies are requested to send the dates of their shows, meetings, etc., so soon as possible, in order that they may be included in the Almanac.

An Increasing Trade in Bananas.—Some particulars, which have been published recently, illustrate the great importance and increasing volume of the trade in Bananas. Since 1919, Messrs. Elders and Fyffes have added twenty boats to their fleet of steamers which carry the bunches of fruit. Early in the New Year three more vessels will be commissioned, making thirty-four in all. The chief Banana supplies are grown in the West Indies, Central America, the Canary Islands, and much more recently, Brazil, where it is hoped to increase the areas considerably in the near future. The best of the western Bananas are the fruits of *Musa sapientum* var. Gros Michel, while those from the Canaries are of the dwarfed *Musa Cavendishii*.

Thunberg's South African Plants.—For the meeting of the Linnean Society held on November 17, Mr. N. E. Brown, A.L.S., had prepared a paper on "The South African Species of Iridaceae in Thunberg's Herbarium," but owing to its highly technical character only the introduction was read. In this, Mr. N. E. Brown stated that Carl Pehr Thunberg was born in 1743, and in due course became a pupil of Linné, and afterwards Professor of Botany at Upsala. He made voyages to South Africa, Java and Japan, and after his return published an account of his travels and described the plants he had collected. He sailed from Europe on December 30, 1771, and landed at Cape Town on April 17, 1772, the journey occupying fifteen weeks, in contrast with the three weeks it now takes to accomplish. Thunberg stayed in South Africa nearly three years, and sailed to Java on March 2, 1775. During his stay in South Africa he made three extensive journeys into various parts of it, and in two of them was accompanied by Francis Masson, who was sent to collect living plants for the Royal Botanic Gardens at Kew, and who first introduced many of the South African plants that now adorn our gardens and greenhouses. Thunberg sent or brought back from the Cape a large collection of dried plants which he had discovered, and described then in numerous separate pamphlets and in his *Prodromus Plantarum Capensium* and *Flora Capensis*. Many were described also by the younger Linné. This fine collection of well-dried specimens is now preserved in the Botanic Garden at Upsala.

Tree Vandals in Rome.—The amenities of the most fashionable part of the city of Rome have suffered a grievous injury through the depredations of a gang of hooligans. It seems that these evil-disposed persons entered the city a fortnight ago, soon after midnight, and cut down fifty of the finest trees in the noted Sycamore avenue, in the Via Veneto, and departed before day-break. These trees, which grew between the former Dowager Queen's Palace and the Pincio Gate, were planted about sixty years ago, and the tallest specimens spread their branches above the principal residences.

Plane Trees in the Mall.—Although a good deal of nonsense has been written about the Plane trees in The Mall, it is quite evident that many Londoners take a very keen interest in the four rows of trees that extend from the Duke of York steps to the Victoria Memorial. It must be obvious to those who are acquainted with the growth of trees in the London area that the roots of the Plane trees in The Mall have now reached a less kindly soil than that in which they were planted and, naturally, growth is less vigorous than in former years. In all probability, however, so soon as the roots have made themselves familiar with the gravelly subsoil, growth will again improve, and it may not be very many years hence when it will be necessary to remove half the trees to allow the other half to develop. Many readers of *The Gardeners' Chronicle* will remember the fierce controversy which took place about sixteen years ago concerning the management of these self-same trees. The controversy was, however, brought to an end when the late Sir Isaac Bayley Balfour, at the request of the Govern-

* Report of the Development Commission for the year ended 31 March, 1927. H.M. Stationery Office. Price 3s. net.

ment, made a report on the subject, and proved that the arboriculturists and horticulturists concerned had applied sound practical knowledge combined with scientific principles to the pruning and general management of the Plane trees in The Mall.

A Quaint Indian Horticultural Advertisement.—

A Calcutta correspondent has sent us a copy of a quaintly amusing advertisement distributed by an Indian firm of florists and seedsmen. The enthusiastically descriptive inducement to purchase Araucarias and Cyresses is worded as follows:—"Besides the grandeur, Araucaria and Cypress trees bring exquisite pleasure at the very outset to one and all at first sight near Colleges, play-grounds, new extensions in the vicinities of populous and growing cities. And any garden or park devoid of these plants look like a barren forest fit for moping owls; while, on the other hand, any pleasure place or bower embellished by majestic conical Araucaria, birds chirping on them with melodious songs, makes hell a Heaven. Hence the pleasure that the public derive from gardens, parks or any places of recreation adorned by these evergreen trees is immeasurable and inestimable, and as such their planting is essential and indispensable."

The Cuckoo's Secret.—Following the Horticultural Club Dinner, to be held at the St. Ermin's Hotel, Westminster, on Tuesday, December 13, at 6.30 p.m. for 7 p.m., a lecture will be given by Mr. P. F. Bunyard, F.Z.S., entitled "The Cuckoo's Secret Solved." The lecture will be illustrated by lantern slides.

Belgian Florists' Social Evening.—On Saturday evening, November 19, the Belgian Florists' Association held its annual banquet and dance at the Royal Tavern, in Brussels. The tables were superbly decorated, and many important people in the horticultural world graced the gathering by their presence, including M. Van de Weyer, the President of the Association; M. Foreau, President of the Syndical Chamber of Florists in Paris; M. F. Spaë, President of the Organising Committee of the Ghent Florales, and M. Charles Pynaert. A large company partook of the banquet, and danced at the ball which followed.

Oxford Preservation Trust.—Thanks to a loan from one of its friends, the Oxford Preservation Trust has been able to acquire a portion of the Foxcombe Estate, Boar's Hill, whence a beautiful view of Oxford is obtained. About £5,000 is required, however, to complete the purchase price of £11,000. Ample additional funds are needed also for the purpose of preserving the belt of meadow and park land which surrounds the centre of Oxford, and for purchasing other tracts of land than those at Boar's Hill, from which views of the University City may be obtained.

Chrysanthemum Midge.—The attention of the Ministry of Agriculture has been drawn to the appearance in certain glasshouses in the Lea Valley of the Chrysanthemum Midge (*Diarthronomyia hypogaea*, F. Low), described and illustrated in *The Gardeners' Chronicle* of November 12, last (pp. 388, 389, Figs. 174, 175, 176, 177). This Midge has been known to exist in Europe on the wild Ox-Eye Daisy, but until this year it has not been known to attack Chrysanthemums in this country, though it has been a trouble to Chrysanthemum growers in the United States for some years. The Ministry states: "There is reason to believe that the pest was introduced from abroad in cuttings of the variety Monument, and all growers who have received cuttings of this variety from abroad, or from the Lea Valley district during the last two seasons, are asked to examine their plants, and if they find any suspicious galls on the stems or leaves to report the fact at once to the Ministry. The most noticeable feature of an attack by the midge is the presence of small galls or growths on the leaves. The galls are cone-shaped, about one-twelfth of an inch long, and project obliquely from the surface of the leaf. The chief risk of a spread of the pest is through the medium of infested cuttings, and it is hoped that with the co-operation of Chrysanthemum growers it may be possible to discover all existing

cases and to exterminate the midge whilst its distribution is still somewhat limited. In order that the Ministry may be in a position to require preventive measures to be taken, should occasion require, an Order has been issued adding the Chrysanthemum Midge to the list of pests included in the scope of the Destructive Insects and Pests Order of 1922, and requiring imported cuttings and rooted parts of Chrysanthemums to be accompanied by an official Certificate of freedom from the pest."

Mr. Frederick J. Rose.—When commencing his gardening career under his father at Saltwood, Hythe, Kent, Mr. F. J. Rose met the late Lord Swaythling (who died in June of this year) who took a special interest in him and expressed the hope that at some future time he might employ him. At the age of seventeen, Mr. Rose became journeyman at Cobham Park, Surrey, under Mr. W. H. Honess (now of Walhampton Park, Lymington), and here he stayed for two years. Then followed a short stay at Welbeck, under the late Mr. Roberts, and from Welbeck he went to the Oxford Botanic Garden under Mr. W. G. Baker. Here he was perfectly

MR. F. J. ROSE.

happy and remained for just under a year, when Lord Swaythling (then Mr. L. S. Montagu) wrote offering him a position in his father's (then Sir Samuel Montagu) garden at South Stoneham House, Southampton. At first Mr. Rose was very undecided, but eventually accepted the offer and went to South Stoneham in November, 1905. In 1911, thanks to the generosity of his employers, he served at Gunnersbury House, under Mr. James Hudson, for six months, where he had every opportunity of gaining knowledge, not only from those well-kept gardens, but also by visiting Kew and other gardens in the vicinity, and the Royal Horticultural Society's fortnightly shows at Vincent Square. The first Lord Swaythling died in January of that year, and Mr. Rose returned as foreman to Lady Swaythling, who remained at South Stoneham House. Mr. T. Hall retired at the close of 1915, and Mr. Rose then took charge of the gardens, but a few months later he joined the 4th Hants. Regiment and was drafted to India, Mr. Hall returning to his charge. During two-and-a-half years' service in India he suffered severely from nephritis and enteric fever, and as a consequence of his illness he was eventually transferred to the garrison battalion of the Bedford Regiment, while his own regiment went to Palestine and afterwards to France. Mr. Rose was invalided home immediately after the Armistice, and in February, 1919, again resumed

his duties at South Stoneham. The first Lady Swaythling died two weeks after his return, and South Stoneham was placed on the market. At the completion of the sale, the late Lord Swaythling offered Mr. Rose the charge of the gardens and farm at Townhill Park, adjoining South Stoneham, a position he accepted and has held ever since. Here he has had the pleasure of supervising the laying out and planting of new walled-in kitchen gardens and orchard, and the building of plant houses and vineries. In the late Lord Swaythling he had a sympathetic and generous employer who was keenly interested and found great pleasure in his garden. The two worked together in perfect harmony for six years, enlarging the gardens and creating a collection of many of the most interesting and beautiful of the new shrubs, including the best species and hybrids of Rhododendrons; this work, fortunately, is being carried on by the present Lord Swaythling. Mr. Rose has achieved considerable reputation locally for the cultivation of Sweet Peas, hardy flowers and Grapes, but his time is so fully occupied that he has little to spare for exhibition work.

Legacies to Gardeners.—Mr. Rowland Douglas Todd, of Greswolde House, Birmingham, who died on December 2, 1926, bequeathed £100 to his gardener, Mr. J. Bowler, if still in his service. The Earl of Winchelsea, of Haverholme Priory, Sleaford, who died on August 14, leaving unsettled property of the gross value of £13,754, bequeathed £100 to his gardener, Mr. W. Kneller.—Dame Mary Anne Quilter, of Woodhall, near Woodbridge, Suffolk, who died on September 12, leaving estate valued at £42,715, bequeathed £50 to her gardener, Mr. Brown.—Mr. W. Stewart, of Brodawel, Caerleon, who died on September 3, leaving estate of the value of £36,101, bequeathed £50 to his gardener, Mr. W. Young.—Miss M. E. Chavasse, of Alton Place, Wylde Green, Warwick, who died on October 8, leaving personal estate of the gross value of £12,723, left £50 to her gardener, Mr. George Cross.—Mr. Alex. Crossman, of Hill House, Harrow Weald, who died on October 9, bequeathed £50 to his gardener, Mr. Maline.

Mr. John Ramsbottom.—Following the promotion of Dr. L. J. Spencer to the position of Keeper of Mineralogy, Mr. John Ramsbottom has been appointed a Deputy Keeper of the Department of Botany, Natural History Museum, South Kensington.

Bird Sanctuary on Eel Pie Island.—It is reported that a part of Eel Pie Island—a well-known beauty spot and boating centre on the River Thames, near Twickenham—is to be fenced off and reserved as a sanctuary for birds.

Presentation to Mr. and Mrs. George Woodward.—Our friend and coadjutor Mr. J. George Woodward, The Gardens, Teston, Maidstone, has completed fifty-years service on the Barham Court Estate and to celebrate this event, Mr. and Mrs. Woodward, together with other employees and friends, were entertained to lunch at Barham Court by Sir Charles and Lady Warde. Presentations were also made to Mr. and Mrs. Woodward and in making them Sir Charles Warde acknowledged the loyal and faithful services rendered to himself and Lady Warde by Mr. Woodward and referred to the splendid services their guest had rendered to the parish and district. Sir Charles stated that "thanks to my friend Mr. Woodward" they had a splendid working Men's Club of which the founder was Hon. Sec. and Treasurer for twenty-five years; moreover it was due to Mr. Woodward that they possessed a fine Parish Room. But even these efforts did not complete the list of Mr. Woodward's activities as he was still acting as Churchwarden, after thirty-five years' service, was Hon. Clerk to the Parish Council, and Assistant Overseer of the Poor. Mr. Woodward's many friends will join with us in congratulations upon his attaining a jubilee of service at Barham Court, Teston.

The Otari Open-air Plant Museum.—As our readers are already aware, an open-air native plant museum has been established near Welling-

ton, New Zealand, for the preservation of native plants. The reservation consists of 143 acres, about one-half of which is occupied by forest, some of it being practically virgin forest. Much of the area consists of fairly steep slopes, but there are many level places of considerable size, and there is every variety of aspect—a most important feature. The lowest part of the reservation consists of a valley through which flows the Kaiwharawhara Stream, which is crossed by a bridge leading by a natural pergola into the heart of the reserve. The unforested portion will, subject to minor modifications, be devoted to (1) the flora, including both the systematic and biological sides; (2) the vegetation; (3) horticulture; and (4) restoration of the forest. A very interesting account of this open-air native plant

cultural Club meeting of April 5. Those who desire to obtain copies of the *Gazette* should become members of the British Pteridological Society. The Hon. Secretary is Dr. F. W. Stanfield, 120, Oxford Road, Reading.

Appointments for the Ensuing Week.

SUNDAY, DECEMBER 4: Wakefield and North of England Tulip Society's meeting. MONDAY, DECEMBER 5: Harrogate and District Horticultural Association's meeting; Romsey Gardeners' Association's meeting; Birmingham Gardeners' Mutual Improvement Association's lecture. TUESDAY, DECEMBER 6: Bolton Horticultural Society's lecture; Royal Caledonian Horticultural Society's meeting. WEDNESDAY, DECEMBER 7: Nottingham and Notts. Chrysanthemum Society's meeting;

It is not a species, but an accidental hybrid, supposed to have sprung up between the common China Rose and the red Four-Seasons. Some of your readers will doubtless remember the Rose Ile de Bourbon, or Bourbon Jacques—for under both these names it was disseminated; and it is from this Rose, variously hybridised, that all the Bourbon Roses have been obtained. For the first few years, most of the seedlings raised were of the same colour as the original; some were finer and many more double; one of which, Augustine Lelieur, remains a good Rose to this day. The first variation was the production of kinds of a clear and beautiful silvery tint, then of a dark purple and crimson hue, till now we have flowers as brilliant in colour and equal in form, to almost any Rose. The Bourbon Roses generally are hardy and easy of

FIG. 198.—PINUS RADIATA AT PAIN'S HILL, COBHAM, SURREY.

(see p. 443).

museum has been written by J. G. MacKenzie, Director of Parks and Reserves, Wellington, and L. Cockayne, Honorary Botanist, New Zealand Institute of Horticulture, and is published in the form of a *Bulletin* (Vol. 1, No. 4) of the New Zealand Institute of Horticulture. The account is illustrated with views of the original forest, flat portions of the area, climbing plants, and the proposed site for an alpine garden.

Hardy Ferns.—Lovers of hardy Ferns will find much interesting and useful matter in Vol. V, No. 8, of the *British Fern Gazette*, recently published by the British Pteridological Society and edited by Dr. F. W. Stansfield. A few of the more important articles are those on Mendelism in Ferns, *Lastrea Filix-mas variegata* and its Varieties, and a resume of Mr. W. B. Cranfield's lecture given at the Horti-

Sheffield Chrysanthemum Society's annual dinner; Wimbledon Gardeners' Society's meeting; London Gardens Guild lecture. THURSDAY, DECEMBER 8: London Gardens Guild lecture. FRIDAY, DECEMBER 9: East Anglian Institute of Agriculture's lecture; Royal Horticultural Society of Ireland meeting.

"Gardeners' Chronicle" Seventy-five Years Ago.

The Bourbon Rose.—About thirty-five years ago, a French botanist, M. Breon, visited the Island of Bourbon, and found growing in a garden at St. Benoist, a Rose altogether new to him. The flowers were rosy-carmine, beautifully cupped, and the petals remarkable for their size and smoothness. Our botanist did not fail to appreciate this *nouveauté*, and sending it to Paris, it was there multiplied and scattered abroad; this was the original Bourbon Rose.

culture; the short-wooded, free-blooming kinds, require two annual dressings of manure and close pruning; they are then the most beautiful of autumn Roses, flowering better and more abundantly late in the season than in summer, fine flowers often expanding at the end of October. *W. Paul, Gard. Chron., December 4, 1852.*

The Week's Work.

THE ORCHID HOUSES.

By J. T. BARKER, Dunstable, Bedfordshire.

Oncidium cheiroporum.—This desirable Orchid, one of the prettiest and most useful of all the small-flowering and dwarf-growing members of the genus, usually blooms during the late autumn and early winter, and although the bright, Buttercup-yellow flowers are small, they are produced abundantly upon arching spikes, and have a delightful fragrance. This species is easily cultivated, thriving well in small pans suspended from the roof in a cool, intermediate house. It dislikes disturbance at the roots. The best possible time to repot the plants is when the new growths are about to push forth new roots, as at this stage they receive the least possible check.

Cypripediums.—The warmth-loving Cypripediums, such as *C. Stonei*, *C. philippinense*, *C. Lowii*, *C. Parishii*, *C. Rothschildianum* and the numerous hybrids, such as *C. Morganiae*, *C. l'Ansoni* and *C. Shillanum*, which were repotted a few weeks ago, will now have rooted through the new material, and need water at the roots whenever they become dry. Those of the same section which were not repotted will be growing strongly and will need water at the roots frequently. The winter temperatures and conditions should be strictly observed. Syringing and spraying is not to be recommended during the winter as water is liable to settle inside the growths and cause decay. Although these plants require plenty of moisture at the roots whilst in active growth, an excess must be carefully guarded against. Most of them have thick, leathery foliage and are capable of withstanding a moderate degree of dryness at the roots. It is much easier at this season to wet the rooting material than it is to get it dry again, and a saturated medium means the loss of many valuable roots. Where Cypripedium flowers are appreciated, these summer-flowering kinds are valuable. Although they are not grown to the same extent as those of other sections, they are worthy of cultivation.

Winter-flowering Cypripediums.—These are now in full bloom and will continue to make a display far into the New Year. Varieties of these useful Orchids are very numerous, and improvement continues both in regard to the size, form and colour of the flowers. Some are appreciated more than others, whilst some adapt themselves better to the decorator's art than others, yet all are beautiful, and as winter-flowering subjects they are unrivalled for their lasting qualities, either as cut flowers or as plants for decorative purposes. Being of easy growth their culture may be undertaken by anyone, and in foggy districts, near large cities, there is no plant grown under glass that will better repay the trouble taken to grow them satisfactorily.

THE KITCHEN GARDEN.

By R. H. CROCKFORD, Gardener to THE RT. HON. LORD WAVERTREE, Horsley Hall, Gresford, N. Wales.

The Onion Bed.—The site for next season's Onion crop having been chosen, no time should be lost in deeply trenching and liberally manuring the soil. Onions are deep-rooting subjects, so much so that I have, on more than one occasion, found roots at a depth of three feet. This suggests that, where possible, the ground should be trenched at least two spits deep. If the subsoil has seen daylight before, by all means bring it to the surface; if not, and if it consists of clay or gravel, it should be stirred deeply and receive additions of well-rotted manure, burnt garden refuse, road scrapings, or anything else that will improve it and make an extra larder for the roots to obtain food from. This principle of deep manuring holds good,

whether the soil is trenched or only bastard trenched; I would even fork manure into the third spit, for the deeper the soil is moved the sweeter it will become; moreover, by allowing stagnant water to drain away more freely during a wet season such as the last, such soil becomes warm, while during a very dry, hot season the roots can penetrate more deeply, thus enabling the crop to withstand the effects of a prolonged drought without suffering to any degree. As the work of trenching proceeds more manure should be mixed with the soil, but this should not be placed less than one foot below the surface, or the Onions will become thick-necked. Leave the soil surface as rough and loose as possible so that the weather may act upon it. If the ground is very tenacious the top spit should be ridged. When trenching is finished, a good dressing of basic slag, at the rate of four ounces to six ounces per square yard, should be strewn over the surface; this will be washed down during heavy rains. Soil requiring lime should be dressed with this material next February, and afterwards lightly forked over.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to SIR CHARLES NALL-CAIN, Broomfield Hall, Hertfordshire.

Chrysanthemums.—As these plants pass out of flower the stems should be cut down to within eight inches of the pots, after which they should be stood on a bed of ashes in a cool house to furnish cuttings for propagation. Green fly is very partial to the young shoots, therefore it is always advisable to spray the plants with Quassia extract or some other useful insecticide to keep the shoots clean. Should mildew appear, dust the leaves with flowers of sulphur. To be successful in rooting Chrysanthemums it is necessary that the cuttings are free from both these pests before any attempt is made to propagate them. Precautions taken now will prevent disappointment later on. Late-flowering varieties should be placed in a light position in a cool house and fed occasionally with weak liquid manure.

Palms.—These are usually grown in comparatively small receptacles, consequently they will need assistance, such as liquid manure or a fertiliser to preserve the rich green colour of the foliage. Weak soot-water applied to the roots frequently will do much to promote good colour. Now is a suitable time to cleanse all Palms by sponging them with soapy water or an insecticide.

Bougardias.—These plants may be had in flower at almost any time. If early flowers are required more heat should be afforded. A low-roofed house in which the plants are kept near the roof-glass and fully exposed to light will suit them providing there is a moderately moist atmosphere.

Begonia Gloire de Sceaux.—This fine plant delights in plenty of heat and moisture during the time it is making its growth. For the present, all flowers should be removed so that strong plants may be produced before they are allowed to bloom in the early spring. The receptacles in which they are growing should now be well-filled with roots, and the latter will need some assistance in the form of liquid manure. Any check caused now by semi-starvation will become evident when the plants come into bloom. Once growth is completed a little less heat and moisture will suffice. As fog is a great enemy, the ventilators should be kept closed so long as it continues. Attend to the necessary staking as the growths develop. *Begonia nitida* will require much the same treatment as recommended for *B. Gloire de Sceaux*.

Souvenir de la Malmaison Carnations.—Young plants of these Carnations, raised from layers during July and August of the present year, and growing in sixty-sized pots, may be transferred to pots six inches in diameter, in which they may be allowed to flower.

The compost for this final potting should consist of good, open loam, but should the loam be of a heavy nature, a little spent Mushroom-bed manure may be added, after passing it through a fine sieve; also add wood-ash, old mortar-rubble and coarse sand. Pot with medium firmness and when the work is finished stand the plants in a cool, airy house, using only sufficient fire-heat to expel damp. Water the plants sparingly during the dull winter months.

HARDY FRUIT GARDEN.

By H. MARKHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet, Middlesex.

Cordon Pears.—The finest and best Pears are usually produced by trees trained against walls or wooden fences, provided the roots are in a good soil and the trees well looked after. The drainage should be ample, especially where the land is heavy. In many gardens, large and small, there are vacant spaces on walls or fences which might be utilised for Pears and choice Apples with excellent results. There is no other way in which such space can be so quickly and profitably covered as by planting suitable double or single cordons worked on a surface-rooting stock. In this way many varieties may be grown in a limited space. If single stemmed plants are chosen these should be planted eighteen inches apart; if double-stemmed, allow a distance of three feet between them. Do not plant trees too near the wall or fence, but allow sufficient space for the future development of the stems. Overcrowding is often a cause of failure, especially if the trees are allowed to lengthen their spurs year after year, as they cannot develop strong flowers, leaves or fruit buds when the spurs are thickly placed.

Pruning.—Large cordon trees that are in a full bearing condition should be pruned. Remove all old snags and thin out some of the spurs. When pruning Pear trees extra care is needed for varieties whose fruit buds are produced on shoots several inches in length. All shoots required to form fruit buds should be cut back to within a few buds of the base. Those required for extension may be left from twelve inches to fourteen inches in length, cutting them just above a suitably placed bud.

Top-dressing.—All fruit trees that are worked on a surface-rooting stock should receive every encouragement to keep them in perfect health. Feed the roots liberally during the summer with liquid manure, and apply heavy mulchings of decayed manure in dry weather. At the present season good top-dressings of fertile soil, with the addition of bone-meal, will greatly benefit the trees and help to increase the quality of the future crop.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to COLONEL SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Strawberries.—Growth having ceased, the plants will not derive further benefit from exposure to heavy rains. The main stock will remain plunged up to the rims of the pots, but plants intended for starting within the next few weeks should receive the shelter of a cold pit, from which the lights may be removed on fine days. Where a regular supply of forced fruit is imperative, a proper Strawberry house should be provided. Assuming that the Strawberry house is ready, the shelves may at once be filled with suitable varieties. The temperature through the first stage need not exceed 40° to 45° by night and 50° through the day. Kindly weather will very often favour the maintenance of these temperatures for some time, but, as free ventilation is necessary, the hot-water pipes may be warmed during severe weather. It is a good plan to have the pipes warm in the early morning and then water the plants and, if necessary, syringe the foliage; but much as the

Strawberry enjoys root moisture, tepid water must be carefully and judiciously used through the early stages of forcing.

Cherries.—If the earliest trees have not been housed no time should be lost in getting them cleansed and placed in position for forcing. Like Strawberries, they are most impatient of fire-heat and close confinement, no matter how light or suitable the house may be. The same degree of heat and the free circulation of air that suits the Strawberry will also suit the Cherry, and not a few growers provide good shelves where they will not impede the light, and force Strawberries together with Cherries. When pot Cherries are introduced the soil should be rammed firmly about the roots when fairly dry, watered with lime-water to expel worms, and top-dressed with loam enriched with bone-meal. If the weather is moist and mild all the ventilators may be left open by night and day, and later, when the buds show signs of swelling, a good substitute for fire-heat is the introduction of a body of fermenting material thrown loosely amongst the pots, where it may be turned and renovated as necessary; the warm vapour from this will be found more genial than moisture from the syringe.

Plums.—These, like Cherries, must be kept cool and the house well ventilated if they are under cover. Where proper attention was given to pinching during the period of growth there will be little pruning necessary beyond trimming rough cuts. See that the trees are cleansed as a safeguard against insect enemies, and top-dress the soil with loam, lime-rubble and bone-meal after removing the surface soil.

THE FLOWER GARDEN.

By JOHN COUTTS, Assistant Curator, Royal Botanic Gardens, Kew.

Dry Wall Gardening.—It is generally conceded that it is not necessary to have a rock garden to successfully cultivate effective alpine plants, as many of them will do quite well on the level ground, especially as edgings, where stones are used to hold up the soil in the front of a border. Many alpine plants of a prostrate habit, however, dislike excess of moisture, especially during the winter months, and for such subjects dry walls afford an ideal means of cultivation; indeed, very many plants are much happier under such conditions than in the average rock garden. Thus, on steep, sloping ground, where it is necessary or desirable to build retaining walls, there may be a dry wall that affords a ready means and ideal conditions for the successful cultivation of many choice and beautiful plants. Such walls are most pleasing when built of stone, but low walls may be of brick, with openings for plants, while along the top there may be fairly strong-growing plants of drooping habit; they soon present a pleasing appearance. Of course, such structures are not strictly dry walls; a dry wall is one built without mortar. In constructing a dry wall it is important to start with a firm foundation, and this is especially important if the wall is of considerable height. The stones should be slightly tilted towards the back, firmly bedded, and packed with soil as the work proceeds; a distinct advantage follows if the plants are inserted as the work of construction advances. Small, choice subjects should not be placed where they may be over-grown by stronger growers. Many natives of warm, dry countries are perfectly hardy and flourish on dry walls, whereas on the average rock garden they suffer from winter damp. Plants of a spreading or drooping habit are best for furnishing such walls, while those of a rosette or tufted habit find a congenial home therein, including the Saxifragas. Others that may be mentioned are Acantholimon, Achillea, Alyssum, Aethionema, Androsace, Arabis, Aubrietia, Campanula, Coronilla, Dianthus, Dryas, Erodium, Helianthemum, Iberis, Lithospermum, Onosma, Phlox, Saponaria, Sedum, Sempervivum, Thymus, and Veronica. Where a plant does not succeed in the rock garden, it is a good plan to test it on a dry wall.

FOR NORTHERN GARDENERS.

By A. T. HARRISON, Gardener to the MARQUIS OF AILSA, Culzean Castle, Maybole, Ayrshire.

Primulas.—The many beautiful varieties of the Chinese Primula are now making the greenhouse gay, and should be arranged in batches of one colour to be thoroughly effective. The Stellata forms are very useful plants for many purposes, and quite useful and neat specimens may be grown and flowered in four-inch pots, if given an occasional dressing of soil and manure, or regular supplies of liquid manure. Larger specimens may be grown if they are repotted into six-inch pots, and these, if the flowers are once more picked off, will provide a succession of flowering plants early in the New Year.

remains mild and open, although all are agreed that earlier planting is to be preferred, as this allows the recently moved plants to become partially established before winter sets in. The main conditions to be observed, however, are that the soil is in good working order, neither frozen nor lumpy, nor wet and sticky after rain, and that planting is completed at an early date.

Celery.—The final earthing-up of this crop should now be completed and preparations made to give additional protection should hard frost set in, by placing bushy Spruce branches along the rows. These are readily put into position over Celery and as speedily removed when not required, and are capable of warding off the effects of quite sharp frosts. When a

FIG. 199.—NICANDRA PHYSALOIDES.
(see p. 443).

The improved forms of *P. malacoides* are also well worth a trial, as their colours are more decided than in the type, and their stems stouter, and more able to hold the flowers erect. Among these, Advance, Achievement, Eclipse and Courtland's Seedling are recommended as being improved forms of this old favourite. *P. malacoides*, by the way, is much hardier than many believe, and the old plants may, after flowering, be planted out, where they will soon become established and produce another crop of flowers. *P. obconica* is one of the most free and continuous flowering plants in cultivation, but it has a bad reputation in many gardens as the cause of a very painful skin trouble, and should therefore only be grown where it is not likely to be a nuisance.

Planting.—Owing to the somewhat sharp frosts experienced last month, many trees, etc., were not forwarded by the nurserymen, and the delay thus caused must be made good so soon as possible. It is quite safe to plant Roses and fruit trees in December, when the weather

lengthy spell of severe weather is expected, a sufficient number of Celery heads may be lifted and stored in the vegetable shed, where they will remain fresh for a considerable time if the roots are left intact and not allowed to become dry.

Pruning and Nailing.—So soon as the foliage has fallen from fruit trees on walls the necessary pruning and nailing or tying may be attended to. In most gardens, nowadays, the walls are wired, and this greatly facilitates the work, but great care must be observed each season to see that the ties of the previous years are not cutting into the bark. Young, vigorous trees expand their main branches rapidly, and ties must be fairly tight to keep them in their proper positions; such ties must be removed when they become a source of danger. Where nails and shreds are still the main agency in securing wall fruit trees, this danger is not so apparent, but old shreds should also be removed and destroyed, as they form hiding places for the eggs of many insects.

ORCHIDS OF THE MEDITERRANEAN REGION.

PLANT-LOVERS who sojourn on the Riviera during the winter and early spring months are usually interested in the terrestrial Orchids which are indigenous to the countries bordering the Mediterranean Sea. The genera represented include *Ophrys*, *Orchis*, *Cephalanthera*, *Barlia*, *Serapias*, *Anacamptis* and *Aceras*.

A study of these interesting plants usually ends in the student desiring to grow them in his own garden, and a few plants are brought home. Their culture, however, presents certain difficulties, for these Orchids do not adapt themselves readily to the cold and damp conditions of our more northern climate. Such interesting species as *Ophrys Bertolonii*, *O. Speculum*, *O. Arachnites*, *O. Scolopax*, *O. tenthredinifera*, *O. lutea*, *O. aranifera*, *O. bombyliflora*, *O. atrata* and *O. fusca*, *Barlia longibracteata*, *Serapias cordigera*, *S. longipetala* and *S. Lingua*, *Orchis olbiensis*, *O. papilionacea* and *O. pallens* are all worthy of cultivation, and the flowering of any of them affords ample reward for the care necessary for their well-being.

It is practically useless to attempt outdoor cultivation, but the plants may be grown in a cold frame. If, however, they may be accommodated in a Carnation house, the drier and more buoyant atmosphere will suit them better.

The application of water is the most difficult problem in the cultivation of *Ophrys* and *Orchis*, and especially so in the case of the former, for the young growths are tubular, and as the leaves develop they spread out near the surface of the soil until the whole plant forms a natural funnel. It is, therefore, most difficult to water the plants without some of the water finding its way to the centre of the growth, when it is immediately conducted down to the tuber, where, owing to slow evaporation, rotting commences, and in a short time it is possible to pull out the whole growth as its base has completely rotted away. The life of the plant thus depends on whether the new tuber of the current season's growth has already been formed. To avoid this trouble it usually occurs to the grower to partially immerse the pots as a means of supplying water, but again a difficulty arises, for the soil becomes saturated and dries so slowly (during the winter months) that the fleshy roots will probably perish, or their points become blackened and further growth stopped.

I find that the safest way to apply water is to plunge the pots in which the plants are growing into other pots sufficiently large to allow a circle about half-an-inch wide to remain between the rims of the two pots. The outer pot should be as well-drained as the inner one, with a layer of Sphagnum-moss over the drainage on which to stand the pot containing the tubers; the space between the two pots should be packed with Sphagnum-moss, and if this is kept constantly moist the plants will obtain sufficient moisture without direct watering at any stage of their growth.

The rooting medium for *Ophrys* and *Orchis* should consist of good calcareous loam. Species of *Serapias* are not usually found on a limestone formation, and if possible these should be given a lime-free soil, with the addition of some small granite chippings or sharp sand.

The tubers should be potted before growth commences, in pots of moderate dimensions; a four-and-a-half-inch pot will accommodate about four tubers of most of the species, but in the case of such strong growers as *Barlia longibracteata* one tuber will be sufficient. The pots should be well-drained, and if a thin layer of Sphagnum-moss is placed over the drainage it will act as a conductor, if the system of watering recommended is adopted.

Although these species are often termed European Orchids, many of them occur south of the Mediterranean, but the North African forms grow taller and are larger in all their parts than those found in the south of France and Italy; moreover, their vigour is increased in proportion to their size, and this they retain under cultivation. I recommend anyone who is interested in the cultivation of these plants to secure, if possible, these robust Algerian forms rather than those of southern Europe.

It would, however, be a great pity if these plants were collected so freely that they eventually became as rare as some of our British species, and unless a really serious attempt is to be made to cultivate them successfully it is far better to let them grow in the more congenial surroundings of their native home. *F. C. Puddle, Bodnant Gardens, Taly-Cafn, North Wales.*

ORCHID NOTES AND GLEANINGS.

SARCOCHILUS FITZGERALDII.

THIS is one of the most attractive of Australian Orchids, and it was dedicated by Baron Ferdinand von Müller, Director of the Melbourne Botanic Garden, to Mr. Robert Fitzgerald, of Sydney, the monographer of *Australian Orchids*.

The stems are short, usually with three to five linear-oblong, leathery leaves, each three to five inches long; the slender peduncles are drooping, rather longer than the leaves, six- to nine-flowered. The flowers are about an inch in diameter, on white pedicels; the ovary is white, the sepals and petals white, with dense basal spottings of rose-purple. The lip is the shortest segment, saccate, three-lobed, the side lobes erect, white, spotted with purple, the small front lobe being bright yellow; the column is very short.

In *Australian Orchids*, Fitzgerald wrote: "Within the spray of the Naroo falls and the surrounding streams, *Sarcophilus Fitzgeraldii* was found in masses clinging to the dripping rocks, and covering the black basalt with its green roots that stretched for yards over the smooth surface, and followed the mossy crevices. With it were associated a strangely proliferous form of *Dendrobium Kingianum* and clumps of *Sturmia reflexa*, while to the small branches of bush and tree clung the little *Oberonia palmicola*, *Dendrobium aurantiacum*, and *Sarcophilus olivaceus*, and upon the fallen trees grew wonderful old plants of *Dendrobium Hillii*. The rich vegetation, black basalt, and white, foaming river, with glimpses through the tops of the trees of the ever-falling water, made one of those rare spots in which the world is forgotten and the longings of the naturalist realised."

Later, Fitzgerald wrote of this Orchid: "It is dependent on insects for its fertilisation. At the Naroo falls many of the leaves were found to be eaten, probably by a species of wood-louse or sand-hopper (*Amphipoda*), which was numerous beneath the clumps; and these insects are, I believe, the principal agents in conveying the little globular pollen masses into the stigmatic chamber."

The genus *Sarcophilus* resembles *Dendrobium* in some respects, but differs from it in the form of the pollen masses and their attachment to a caudicle; the seed capsule and seed are also widely different from those of *Dendrobium*. The interesting and pretty *S. Fitzgeraldii* requires an intermediate temperature, rather subdued light, a moist atmosphere and plenty of moisture at the roots at all times. It may be grown in pans in Sphagnum-moss, or with only a small proportion of fibre. *R. E.*

BULB GARDEN.

EREMURI.

THESE noble plants thrive in a deep, loamy, well-drained soil, and succeed best when planted on a mound or raised bed; they enjoy a position protected from the morning sun and sheltered from high winds.

The wheel-shaped roots may be planted during October or November, and should be protected during winter by means of dry, light material, such as Bracken or Heather.

Eremurus himalaicus, a white-flowered species, was introduced in 1881; the peach-coloured *E. robustus* came from Turkestan in 1874, and from the same district came *E. Olgae* in 1881. Of more recent introduction is the rather dwarf *E. Bungei*, yellow, with orange anthers. A rare species is *E. Korolkowii*, from Central Asia, with a bright rose inflores-

cence. *E. himrob* is a beautiful hybrid. Other desirable *Eremuri* are *E. robustus*, *E. Elwesianus*, light pink; and *E. Warei*, buff-yellow, shot with pink.

Frequent disturbance of *Eremuri* is undesirable. Established plants respond readily to an occasional surface-dressing of rich soil. Propagation is effected by seeds. The garden value of the genus is considerable, and by the use of various species many noble spring and summer effects may be obtained. *Ralph E. Arnold.*

ROSE GARDEN.

ROSE MRS. JOHN LAING.

DURING the last few years I have been repeatedly impressed by the beauty and perfection of this old Rose. It is free-flowering, sweetly-scented, and most of its blooms are of exquisite form. These good points, however, are not so constant on young bushes as on old plants. If this Rose is allowed to develop into a large bush—say, upwards of five-and-a-half feet high, and three feet across—the wealth of beautiful flowers such a specimen will produce is astonishing.

In our kitchen garden there are two or three such bushes. I do not know how old they are, but certainly more than ten years. Very little pruning is done beyond the removal of the dead parts and a tipping of a growth that appears to be excessively strong. Nor has manurial aid of any description been given for several years. Such continuously excellent results for so little expenditure would, I know, make envious some rosarians who have to feed their plants regularly to keep them growing well. I conclude that the strong, moist clay which the roots of our plants have reached is able to supply the needs of the Roses. *C. T., Amptill.*

HARDY FLOWER BORDER.

ERIGERON COULTERII.

ERIGERONS for the garden are now numerous, and most of them are very attractive, either by reason of their habit, flowering beauty or other points. Some of the newer ones, reputedly of hybrid origin, are most beautiful, but few possess quite the colouring of *E. Coulterii*. It comes from moist meadows in California, which indicates that it should not be planted in a very dry position, although it does not follow that it requires a really damp place in our gardens, where the summer climate is so different from that of California. A good loamy soil in the flower border suits it well, but those who can manage plants a foot high, or a little more, in their rock gardens should grow *E. Coulterii* near the base. Its nominal height is about a foot, and it has good foliage and sends up leafy stems, each bearing a solitary white flower, or one of white, touched with blush.

E. Coulterii may be increased by division in the spring or autumn, or seeds may be sown in spring. It is hardy. *S. A.*

DIERAMA PULCHERRIMA.

THIS South African Irid is an uncommon yet particularly refined and attractive plant, its graceful, slender, flower-stems, bearing beautiful, bell-like flowers, frequently reaching a height of five or six feet under good cultivation. *Dierama pulcherrima* succeeds best in a rich, well-worked soil where its roots can ramify freely, and it should be planted in an open, sunny position. When given these conditions it grows with remarkable vigour and freedom.

The genus includes several species, but *D. pulcherrima* is the most useful for garden decorative purposes, and the colour range has been widened in recent years by the introduction of several varieties of considerable merit. *Heron* is an attractive variety with tall, wavy stems carrying rich, wine-red flowers of striking beauty; *Windhover* is a robust and free-flowering variety with deep, lilac-rose flowers; *Kingfisher* is a large-flowered variety with blooms of a beautiful shade of pink; and *Heatherbell* is a very charming variety with flowers of a delicate shade of pink, flushed with deep rose. *A. P. C.*

FLOWER GARDEN.

NICANDRA PHYSALOIDES.

THE Apple of Peru is an old-fashioned plant now rarely seen, except in old-fashioned gardens, in botanic gardens, or where collections of so-called medicinal plants are grown as a matter of interest. *Nicandra physaloides* is a strongly-growing annual, easily raised from seeds sown under glass early in the year, as in the case of many other tender annuals. When planted in fairly rich soil it may grow three feet or four feet tall, and as its habit is somewhat spreading and the toothed leaves are abundantly produced, a well-developed specimen assumes considerable proportions.

The blue flowers, an inch or more in diameter, are very attractive and freely produced (Fig. 199, p. 450) and followed by an inflated, five-winged calyx containing a berry-like fruit. The inflated calyx and fruit closely resemble those of a *Physalis*, hence the specific name.

In some parts of the tropics *N. physaloides* is widely distributed, and in certain parts of the United States of America it has escaped from cultivation and become naturalised over a large area.

Other names for this interesting old plant are *Atropa physaloides* and *Physalodes peruviana*. The species is figured in the *Botanical Magazine* of 1824 (t. 2,458), and the illustration is accompanied by the statement that "The name of *Nicandra* was first given to this genus by Adamson, and adopted by Jussieu, Persoon, and others. Schreber applied the same name to the *Potalia* of Aublet which may occasion some confusion; but it will be better to retain Aublet's original name for his plant than to adopt a new name for this, as Ruez and Pavon have done. It ought, undoubtedly, to be separated from *Atropa*. Native of Peru and Chili; grows very well in the open border; but is best raised in a hot-bed and treated like other tenderer annuals; it may, however, be sown in the spring in the open ground, but will not flower so early."

TREES AND SHRUBS.

PINUS RADIATA.

THE Monterey Pine, a valuable and handsome tree for planting in maritime districts, is easily distinguished from other three-leaved Pines by its slender, soft, flexible, bright green leaves, which are densely crowded on the branches, and by its cones, which are borne on very short, stout stalks, obliquely conical, from four to seven inches long, and of a bright brown colour. The cones are usually borne in clusters of three to five, but are sometimes solitary; they remain closed on the branches for many years, forming an interesting feature on old trees.

Pinus radiata grows rapidly when in a young state; in districts where it thrives it will make two-and-a-half to three-feet of growth in a season. It is of little use as a forest tree, as the timber is soft and brittle. As a tree for ornamental planting it has much to recommend it, being symmetrical while young and of a pleasing green, unless growing in inland districts, where it is inclined to turn brown during winter. The species thrives well on the Norfolk coast; planted in exposed positions during 1904-5, in a sandy loam, the trees are now much superior specimens to those of other Pines planted at the same time.

To appreciate the value of the Monterey Pine for ornamental planting it must be seen as large specimens, such as those growing in the grounds of Castle Kennedy, the seat of the Earl of Stair. The sandy loam and well-drained situation combined with the mild climate and humid atmosphere seems to have been found congenial to them. The illustration (Fig. 198, p. 438) shows a very old tree at Pain's Hill, Cobham, Surrey. This is a picturesque old specimen standing in an isolated position in the Park. The gnarled branches and thick, dark-brown, deeply-ridged bark are most effective. Planting in permanent positions when the trees are small is necessary,

and even then it is advisable to obtain the plants in pots, as they do not transplant well from open nursery lines. *R. F., Wisley Gardens.*

CRATAEGUS CARRIEREI.

THE bulk of the foliage of this fine Thorn persisted until the third week in November, and a few sprays of the best-coloured berries have been cut. These sprays of deep green, leathery foliage and Pear-shaped fruits of yellow and scarlet make a striking decoration for any room. It is undesirable, however, to cut this Thorn severely because it is rather slow-growing, and its handsome, rounded form would be affected. A specimen tree here is about fifteen feet in height, shapely, and decidedly attractive both in flower and in fruit—in fact, the glossy leaves always arrest attention. These are whitish on the underside, obtuse, and so much as four inches long and two inches broad on the best growths.

Crataegus Carrieri is said to be of garden origin, its presumed parentage being *C. mexicana* and *C. tomentosa*. As a well-balanced tree for lawn or open woodland Carrier's Thorn is worthy of recommendation. Being among the

ANTIRRHINUM ASARINA.

ANTIRRHINUM Asarina dies off on ordinary rock work and many people jump to the conclusion that it is not hardy, or else only an annual or biennial. It is, however, a true perennial, but must be grown in a dry crevice between the rocks or in the chinks of a sunny wall. In such places it will live for many years, even in positions where it appears marvellous how plant life could sustain existence. The foliage is wonderfully big for the plant, soft, fleshy, and covered with grey hairs, and formed like that of the Ivy. The fleshy stems are fragile-looking and the flowers which are of a pale yellow, have the lips touched with red. They are produced in the axils of the leaves.

A. Asarina is very easily raised from seeds, which may be procured from several seedsmen in this country. These may be sown under glass and the seedlings put into their flowering positions so soon as they can be readily handled, or they may be sown in the crevices where the seedlings are to remain. Although not a showy rock plant, *A. Asarina* is valuable for such places as have been indicated. By the way, I see it is stated that the correct name of this plant, according to the rules of priority, should be

FIG. 200.—*ARMERIA CAESPITOSA*.

last—if not the last—to cast its leaves, and retaining its berries, often into the New Year, it is an altogether useful subject. *C. T., Ampthill.*

ALPINE GARDEN.

ARMERIA CAESPITOSA.

ARMERIA caespitosa is the brightest gem of the Thrift family and occupies a position in the front rank of alpine plants, but may be grown with comparative ease. It is a native of the mountains of central Spain, where it is to be found at an altitude of from 5,000 to 8,000 feet. In our rock gardens it should be given a small, deep crevice, filled with light, loamy soil, or a sunny position on the moraine. It is also a delightful subject as a pot plant in the alpine house (Fig. 200).

A. caespitosa is a dwarf perennial of densely tufted habit, forming close cushions of rosettes of small, deep-green, needle-like leaves. Early in June the leaves are practically hidden from view by the large, almost sessile, heads of pale pink flowers. *F. A. G.*

Asarrhina Loebelii, but few will be willing to accept this change of title.

IBERIS PINNATA.

UNDER the name of *Iberis pinnata* I received about twenty years ago, a perennial Candytuft, which proved very useful on bold rockwork, being of prostrate habit, with dark green leaves and heads of white flowers. What made it of special value was the fact that, in addition to the mass of flowers it produced in spring, it came into bloom again in autumn and flowered until severe frosts destroyed the flowers. Although received as *I. pinnata*, I could never see any reason for this name, as there was no sign of pinnate foliage, and I now find it stated authoritatively that *I. pinnata* is a plant of annual or biennial habit with the leaves feathered into lobes. At the same time, the *I. pinnata* I have grown is a good plant, although probably only a form of *I. sempervirens*.

SAXIFRAGA COTYLEDON ISLANDICA.

WHILE there are numerous varieties of the noble *Saxifraga Cotyledon*, there is none finer than the one called in gardens *S. Cotyledon islandica* or simply *S. islandica*. It first eman-

ated in this country from the famous garden of St. John's, College, Oxford, and was not long in becoming a favourite among growers of the larger silver Saxifragas, whose handsome rosettes and magnificent plumes of flowers are so striking in the rock or wall garden. It is no disparagement to the magnificent *S. Cotyledon catherhamensis* to say that *C. islandica* outrivals it in the size of its glorious rosettes and in the grandeur of its noble plumes of flowers. Where it does well it forms large rosettes of narrow leaves, sometimes more than a foot across, and throws up immense plumes, so much as four or five feet high, laden and arching over with their abundant, snowy flowers.

Unfortunately, the plant is not a success everywhere, as it does not thrive in a few certain gardens, from some obscure reason. It is not such a determined lime-hater as most of the other forms of *S. Cotyledon*, and has thriven well in gardens where lime was present in the soil. It must, however, have a light compost, with plenty of air and sun. It produces offsets freely enough—a great point in its favour in the case of a plant whose flowering rosette dies after blooming. If grown at all near other Saxifragas of the same section seeds are not likely to produce plants quite true to the parent.

ERYSIMUM PUMILUM.

ERYSIMUMS, or Hedge Mustards, comprise a few species of considerable value in the rock garden, and several of them are fairly well-known. *E. pumilum*, one of the best and neatest, is not among the few which are much cultivated, but it deserves a better fate than exclusion from the garden.

A very high authority has told us that it "is one of the most beautiful of all." It comes from dry, sunny slopes of the Alps (though not found in the Swiss Alps) where it is remarkably neat and pretty. It is much dwarfer than *E. pulchellum*, and only grows about three inches high, forming small tufts of neat, narrow leaves, and throwing up short stems, each carrying a wonderfully large head of pale yellow flowers. So large, indeed, is the head of bright yellow flowers that it practically covers and hides the foliage from view. In the rock-garden, in rich soil, it may exceed its proper dwarf stature, and where this is the case the soil ought to be made poorer and harder, or the plant may be transferred to the moraine, where it will retain the diminutive stature which is one of its charms to the alpinist. It is almost needless to say that it ought to have a sunny place. *E. pumilum* may be propagated by cuttings or raised from seeds, which I observe are offered by seedsmen. *S. Arnott*.

NOTES FROM GLASNEVIN.

THE stormy weather experienced at the end of October and beginning of November was followed by several frosts, the last being so severe as 10°. Since then, mild weather has supervened and plant life shows a very remarkable meeting of the seasons. Certain Roses such as Christine, Koster's Orleans and Ellen Poulsen, grown in beds of one kind for decorative purposes, are as bright and full of flower as beds of Begonias or Zonal Pelargoniums in the height of summer. On the other hand, *Iris unguicularis alba* has been in flower for three weeks, and the ordinary mauve form opened on November 14. *Narcissus Tazetta*, a very old clump which has been kept under observation for many years, has already a few flowers open, the previous earliest record being Christmas week. Snowdrop November, a gift from Sir William Lawrence, opened during the first week of the month; it is a beautiful Snowdrop and a decided acquisition among winter-flowering plants.

The dull wet summer had no ill-effect on the flowering of certain bulbs usually supposed to require considerable ripening. *Nerine Bow-*

deni and the form known as Colossus were never finer, and apparently require no other treatment than to be planted out in well-drained soil and left alone. Some of the clumps have been in position a dozen years and increase in beauty each season. Saxifragas of the apiculata group are very forward, some flowers being open now, while Campanulas of the Portenschlagiana type still show quite a fair number of flowers. Two striking groups are of *Schizostylis coccinea* and its pink variety Mrs. Hegarty. Though one would expect them to demand sunshine, as they come from South Africa, there is no evidence in their present wealth of flowers to show that they resent our dull, grey skies. *Spencera ramalana* flowers most persistently, continuing to throw up spikes of yellow flowers until stopped by continuous frost.

Trees and shrubs are now more remarkable for their fruits, as in Cotoneasters and Barberries, or brightly coloured shoots, as in Dogwood and Willow, than for flowers, but already a few flowers are open on a young plant of *Prunus subhirtella ascendens*, while *Escallonia floribunda*, on a wall, is bearing many handsome panicles of white flowers, and a fair display is still made by *Bursaria spinosa*. The many forms and hybrids of the Strawberry Tree, *Arbutus Unedo*, have never flowered more freely and are among our most valuable evergreens. The old *Laurustinus* (*Viburnum Tinus*) is a valuable winter-flowering shrub, which, if newly-introduced, would create something of a furore. The more recently introduced *V. grandiflorum* is now showing its clusters of pink flowers, and those of *V. fragrans* are becoming increasingly prominent every day.

INDOOR PLANTS.

Lobelia coronopifolia (*Bot. Mag. t. 644*), of which seeds were received from South Africa, was known in gardens a hundred years ago, when South African plants were being introduced, and figured in the illustrated botanical and horticultural magazines of that time. From one to three flowers are produced on a common stalk, six to eight inches in length, and they are pale blue. The deeply-cut leaves are mostly basal, the stem procumbent. Although less floriferous than the many bedding forms of *L. Erinus* and not likely to equal *L. tenuior*, as a pot plant, *L. coronopifolia* is interesting in a botanical collection.

Isoloma amabile, also known as *Tydaea amabilis*, is a singularly attractive greenhouse plant. According to the *Botanical Magazine* (t. 4,999), it was discovered in the cold regions of the Cordilleras at 8,000 to 9,000 feet, in 1855. The figure quoted fails to convey an accurate impression of the colour effect of the whole plant, due to the soft red hairs with which all the parts are furnished, particularly the stem, veins on the lower sides of the leaves, pedicels, calyx and corolla. The flowers are produced on pedicels, several together, from the axils of the opposite, ovate, pointed leaves. The corolla is long, widening towards the mouth, where the lobes are spreading and somewhat reflexed, rose-red in colour, the throat yellow, with red spots. *Isoloma amabile* requires warm greenhouse cultivation during the growing season, and will flower admirably where the temperature may fall to 50°, but it should be allowed to rest in a cool house from which frost is excluded.

Pelargonium Fothergillii is a species or hybrid resembling *P. zonale*. It is figured in Sweet's *Geraniaceae*, Vol. III, t. 226, under *Cicionium*, and is flowering now in the Glasnevin collection where the comparatively large umbel of flowers renders it conspicuous among other species. The lobed, crenate leaves are softly-hairy on both surfaces and show a dark zone. The flowers are numerous and closely arranged in the umbel, salmon-red rather than orange-scarlet, as described by Sweet, *loc. cit.* The habit and colour suggest that *P. Fothergillii* is probably as useful for outdoor ornamental planting in summer as any of the popular modern forms of *P. zonale* and its hybrids.

Podalyria sericea is a member of the Pea family and native of the Cape. A batch of young plants, though not flowering, is conspicuous

among other greenhouse subjects by reason of the beautiful, silvery, silky appearance of the leaves. It is figured in the *Bot. Mag.*, t. 1923, and in the *Bot. Rep. t. 440*, as *Sophora sericea*. The charm of the plant would appear to lie chiefly in the simple, ovate, silky leaves, though the small pink flowers, produced from the leaf axils, are not without attraction. *J. W. Besant*.

DEVELOPMENTS AT WISLEY.

WHEN making a tour of Wisley at the present time a visitor will observe that many practical developments are taking place. One of the most interesting of these is the opening up of the Pinetum by means of a broad grass path from the seven-acre field which contains the collections of trees and shrubs. A vista is being opened up from this point to the Pine woods in the distance, giving an idea of greater expanse than previously existed. In making this part more accessible to visitors, the need for further developing the Pinetum will probably appeal to the authorities, and it is obvious from the appearance of many of the Cedars, Cypressess and Pines already planted that there would be no difficulty in establishing a collection of Conifers which would add an extremely interesting feature to the many Wisley already possesses.

Another interesting alteration in course of progress is one which will give more direct access to the rock garden from the broad, paved path which runs alongside the glasshouses. By clearing a corner of the wild garden beyond the eastern end of this path, a continuation of it is effected in a straight line until it meets the existing path on the lower side of the alpine field leading to the rock garden. I had previously passed this corner without noticing a particularly fine Oak, but with the undergrowth now cleared, this stands out as a superb specimen, showing twenty-five feet of clean trunk and a well-balanced head. When the remainder of the undergrowth is removed there will be a clear view from this point across the alpine field to the rockery beyond.

A good deal of remodelling and replanting is still being carried out in the rock garden for the purpose of giving a better rooting-medium to many of its occupants, and it is obvious from the healthy appearance of the plants in portions replanted last year that the work is being done on practical lines. New frames are also being built in the alpine department showing that there is a continuous increase in the interest taken in what is such a marked feature of present day gardening. *Onlooker*.

EWENNY PRIORY.

THE county of Glamorgan is a land of castles, many of which were erected by Norman lords. Beautiful gardens surround some of them and it was my pleasure to visit one on a recent occasion. This was at Ewenny Priory, the residence of C. G. Turberville, Esq.

Ewenny Priory was completed in 1141. It has known stormy times, for it is said that Cromwell tethered his horses in the ancient church which adjoins the mansion. The outer wall of the kitchen garden, which covers about one acre, is part of the old sentry wall. It is now devoted to the more peaceful art of fruit culture. Cordon Pears, fan-trained Plum and Cherry trees are trained on the wall, and for the most part they look a picture of health. Pears are in great demand at Ewenny, although the trees have not been too fruitful this year, I saw some fine specimens of Doyenné du Comice, Beurré Capiaumont, Winter Nelis, Pitmaston Duchess and Durendieu.

The well-constructed fruit cage contained many good examples of small fruits, but the feature which interested me most was some well-fruited canes of the Raspberry named November

Abundance. The fruits were quite ripe and of good flavour.

Apples do very well at Ewenny, particularly the varieties Lord Derby, Warner's King, Worcester Pearmain, Lane's Prince Albert, King of the Pippins and Cox's Orange Pippin.

Indoor fruits are subjects of great care and I have rarely seen finer Peach trees than those which fill two large houses. Mr. Mitchell, the head gardener, is successful with all the leading varieties, save Duchess of Cornwall, which he finds a shy setter. There are three large vineries, a conservatory and a range of plant houses, the latter well stocked with good plants. No Japanese Chrysanthemums are grown, but a large number of decorative and single varieties are grown for cutting. A batch of Begonia Gloire de Lorraine promises well, and Mr. Mitchell is hoping to have ripe Tomatos next March. His aim is to keep the plants sturdy and, if possible, to set fruit early in the New Year.

As might be expected, the ornamental gardens at Ewenny are very beautiful. Of summer bedding in the old sense there is very little. A wide expanse of turf sweeps across the front of the mansion and well-kept Yew hedges are everywhere. The Rose garden and flower garden lie on the east side of the Priory. All the best Roses and herbaceous subjects are tastefully arranged there. The stream which flows through this part of the estate is flanked by scarlet and white Hawthorns, planted alternately and in spring they provide a lovely picture.

Mr. Mitchell, who has completed twenty-nine years of service with the family, has every reason to be proud of his well-kept charge. Part of his apprenticeship was served in Veitch's nursery, and such well-known gardens as those at Shipley Hall and Tatton Park. Geo. H. Copley, N. D. H.

RAISING NEW VARIETIES OF HYDRANGEAS.

THE raising of new Hydrangeas is engaging the interest of many cultivators, and each year new raisers come forward to make additions to the already large number of existing varieties.

The cultivation of the Hydrangea has become immensely popular, thanks to the eminently decorative qualities of this magnificent plant and to the placing in commerce of varieties with large flowers of vivid colouring, supported on rigid stems. It has become one of the most fashionable of flowering plants, and there are certain growers who specialise in its cultivation, and grow Hydrangeas by hundreds of thousands to supply the markets and florists throughout several months of the year. This popularity is due to the great improvements which have been effected and to the display of new varieties at horticultural exhibitions, where the public is able to judge of the great progress which has been made.

It was in 1908 that M. Lemoine, of Nancy, distributed the varieties Avalanche, Fraicheur and La Lorraine; and M. Mouillère, of Vendôme, gave us Vicomtesse de Vibraye and Madame E. Mouillère, in 1909.

The efforts of raisers during the last few years have chiefly been directed to the production of plants with brightly-coloured or pure white flowers, and also to the increase in size of the "blooms." In regard to the latter, "flowers" measuring 10 cm. and inflorescences of 40 cm. in diameter are to be seen at leading shows. All these improvements are the result of patient work, assiduous care and long and untiring observation.

New varieties of Hydrangeas are obtained exclusively by means of seeds, which may be produced either by self-fertilisation or by artificial fertilisation. Seedlings resulting from self-fertilisation usually differ very little from the seed-parent, so that growers prefer to obtain seeds by artificial fertilisation.

The choice of the seed-parent plays an important part in the production of a variety, and it goes without saying that this choice must not be made on theoretical grounds only: it must be dictated by the results it is desired to

obtain, always bearing in mind the fact that the male, or pollen-bearing, parent, plays a preponderant part in the production of new varieties.

The inflorescence of a Hydrangea is composed of two kinds of flowers: (1) sterile flowers, and (2) fertile flowers. The sterile flowers (Fig. 201, No. 1) more or less large, are composed of well-developed petaloid organs, with an insignificant corolla and more or less numerous stamens, but lacking an ovary; they are not therefore capable of producing seeds. They are more or less coloured, or white, and form the ornamental portion of the inflorescence.

The fertile flowers (Fig. 201, No. 3) are, on the contrary, quite small, and are placed at the base of the pedicels of the sterile flowers (Fig. 201, No. 4). They are more or less numerous, according to the species or the variety in question. For example, in *Hydrangea Mariesii*, which has served as the parent of a number of varieties, they are numerous, and also in *H. petiolaris*, in which the inflorescence is almost totally composed of them. These hermaphrodite flowers thus contain the well-formed male and female organs, and are capable, therefore,

or five months. So soon as they are ripe which may be easily recognised by the brown colour they assume—they are harvested and preserved in a dry atmosphere in paper bags on which the names of the parent plants have been inscribed.

The seeds are sown in the spring, under glass, in March or April. For this purpose very clean pots must be used, filled with well-drained *terre de bruyère* (a kind of peaty leaf-mould). The seeds, of which each fruit contains a goodly number, are very small and elongated, and should therefore be sown on the surface, without being covered by the soil—as in the case of Begonia seeds. The pots are then placed on the staging near the glass. If kept moderately damp and in a temperature varying between 15° and 20° centigrade, germination soon takes place, and small plants are formed rapidly, and may be pricked out into pots so soon as they can be handled easily. When the young seedlings are sufficiently developed they are potted separately in small pots, 7 cm. in diameter, and placed under a frame that is kept air-tight for several days. After this, it will be necessary to admit air freely and even-

FIG. 201.—RAISING NEW HYDRANGEAS.

1, Sterile flower, reduced; 2, bud of fertile flower, $\times 2$; 3, expanded fertile flower, $\times 2$; 4, fertile flower growing at the base of the pedicels of sterile flowers, nat. size; 5, long-shaped fruit of *Hydrangea Triomphe*, $\times 2$; 6, rounded fruit of *Hydrangea Sensation*, $\times 2$.

of producing numerous seeds by self-fertilisation. Artificial fertilisation requires to be done with the greatest care, the first operation necessary being the suppression of the stamens, at the time when these organs are totally enclosed in the flower bud (Fig. 201, No. 2), and always before the pollen is in a dehiscent condition. This delicate operation requires great skill, and must be done with all necessary precautions by the aid of the small forceps usually employed for this work, special care being taken not to injure the ovary. At the end of three or four days after the removal of the stamens, the stigmas are generally sufficiently developed and ready to receive the pollen from the plants chosen to be the male parent, and taken, so far as possible, from the stamens of sterile flowers.

A short time after the pollen has been applied, with the aid of a small brush, to the stigma of the flower, the petals fall, the ovary begins to swell, and the fruits develop normally. The fruits assume different shapes, according to the variety; they are sometimes spherical or rounded, as in the variety *Sensation* (Fig. 201, No. 6), sometimes more or less long, as in the variety *Triomphe* (Fig. 201, No. 5).

Plants carrying the fertilised flowers should be placed in a well-ventilated house, and lightly shaded when the sun is hot. Under these conditions the fruits attain their complete development and ripen, usually in about four

tually to expose them to full air and sunshine whenever the weather permits. From this point, the young Hydrangeas may be treated exactly like cuttings; for instance, they may be repotted into pots measuring 10 cm., and then into larger ones of 15 cm. towards the middle of August. A month later, the plants have attained complete development, and the flower bud is already formed. They are at that stage single-flowered specimens if they have grown normally, or multi-flowered if the growths have been pinched in June. When there is danger of frost the plants should be placed under cover, either under frames, or better still, in a cold house, near the glass; this permits of their being brought into growth early, and they will then flower magnificently about May 15 to 20, i.e., a little more than a year after the seeds were sown.

Cultivated in this way, Hydrangeas become practically annual plants, since eighty per cent. to ninety per cent produce their flowers the first year. The raiser therefore concentrates all his attention on these young plants, for if he has done the crossing cleverly he is repaid for all his trouble by the satisfaction of obtaining new varieties of real merit. But it is necessary to eliminate all but the very best plants, retaining only those that may be classed among "plantes d'élite." H. Cayeux, Director of Parks and Gardens, Le Havre.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C. 2.

Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.

Urgent Communications.—If sent by telegraph, these should be addressed "Gard. Chron.," Rand; or by telephone, to Gerrard, 1543.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Letters for Publication as well as specimens of plants for naming, should be addressed to the EDITORS, 5, Tavistock Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.

MR. F. KINGDON WARD'S NINTH EXPEDITION IN ASIA.*

XX.—BACK TO WORK.

SEPTEMBER 3, then, saw us ascending the first range from the eastern edge of the plain once more, in pouring rain, as usual; and I registered a vow that I would march right through to Assam, and never travel this hateful jungle path again. While in Fort Hertz I had received the expected letter from the Government of India stating that, so far as they were concerned, I might follow the Lohit route at my own risk, but I must not look to them for help if I got into difficulties; and the difficulties were simply that there was no food or transport *en route*—which meant for three weeks. I knew that already, so all was well. Curiously enough, when my wife arrived in Rangoon, in December, and heard that I was missing, she wisely told the local Government that I was probably coming by the Assam route, and would turn up presently; the reply was, that I could not be coming by that route because it was quite impossible to get through! Curious things, Governments; they mean well. So far as the Tisang river all went well; then we had to change coolies, and a day was lost, after which we went on to the Nam Tamai without a halt. It was now September 11.

I went on collecting, and found a number of interesting things in the dense jungle, including a good *Clerodendron* and a creeping epiphytic *Gesnerad* with bright scarlet, tubular flowers and small, fleshy leaves. A *Cypripedium* was in bud on the bank, and there were a few other Orchids, such as a *Dendrobium* with salmon-pink flowers. It was rather too early yet for fruits to be strewn on the ground, indicating the forest trees met with, but I noticed a few of *Castanopsis* and certain *Dipterocarpeae*; and I picked up a solitary fruit of a *Magnolia* at about 6,000 feet, although I could not find the tree. In some places Bamboo seeds, nearly as big as Hazel Nuts, were scattered over the ground; the

Nungs collected these and roasted them for their supper. Whenever we came to cultivation the coolies searched amongst the crops for

FIG. 202.—NATIVE HUT ON THE NAM TAMAI.

Cucumbers, and helped themselves liberally; apparently such communism is customary amongst primitive man! The Cucumbers were most refreshing, anyhow.

September 8 was very nearly my last day on this expedition. The weather was particularly hot, and I was waiting for tea at the end of the march, sitting in the shade of the hut, which stood on tall stilts, about five feet off the ground. The coolies were squatting outside with their

the door and out on the verandah, now tilted at an alarming angle; the ladder—a notched log—was gone, and I leapt blindly. Once before, many years ago, on the Burma-China frontier, I had heard a similar sound, and I knew instinctively what it meant; one of the heavy timber beams supporting the immense weight of sodden thatch had broken, and after that, of course, the whole hut simply collapsed flat, like a house of cards. The moment I hit mother earth, that roof spread-eagled; everything happened with amazing swiftness. One minute I was sitting quietly reading on the springy Bamboo floor of the hut; before the end of the same minute I was picking myself up from the ground, contemplating a flattened mass of thatch and beams. An instant's delay, and I should have been crushed and smothered. Whether an earth tremor had shaken the thing down or whether it had just simply collapsed—houses do, sometimes, even in London—I cannot say. I once saw half a Maru village destroyed, on the China frontier; but that was due to a whirlwind.

There was luckily no further delay at the Nam Tamai, and we continued the march up the valley stage by stage, arriving at the Seinghku confluence once more, on September 17. I tried a double march one day, but all the girl porters pretended to be lame, and refused to go on, so I dismissed them; much to their chagrin, replacing them with youths.

Meanwhile, fresh species of *Impatiens*, *Begonia* and other genera were continually cropping up. *Asystasia* sp., with lurid purple flowers, was frequently seen on the edge of the jungle, and a straw-yellow *Strobilanthes*. *Zingiberaceae* were practically over, but *Labiatae* were beginning to appear as big coarse weeds; many species flower in the alpine meadows towards October, and the same species may be found in the open spaces far down into the forested region. *Ficus* *Cunia* furnished me with a little fresh fruit; the Figs are borne on long, thin, whip-like shoots which grow thickly from the base of the trunk, in a matted tangle. They are no bigger than a Walnut, but when rosy and ripe, delicious.

It rained steadily most days, though occasionally we had a fine morning or a fine afternoon; but the river had fallen a lot, so evidently the rainy season was slackening.

Arrived at the Seinghku, the Tarons and others decided that they could not march next day. However, I could not afford to lose a day now, and told them they would just have to, so they did. Flowers began to increase again, but I found little that was new to me, although I collected a couple of rather striking *Zingiberaceae*, with fragrant flowers, two Orchids, two *Begonias*, and other things. There had been something of a lull in blood pests, particularly leeches, but at this camp, which was in an open meadow, sand flies were as common as Blackberries.

While searching for a few capsules of the social 'Irroratum' *Rhododendron* on the hogsback next day, I observed several interesting plants. My attention was first called to a solitary big-leaved, tree *Rhododendron*, stuffed with large bunches of rust-red capsules; from its general appearance, and the large leaves leaning downwards, I judged it to be a 'Grande,' and I sent a man up to the top to hack off a few branches. Imagine my delighted surprise to discover that it was an 'Irroratum'—the capsule and leaf, despite its great size, admitted of no doubt. Most of the Burmese 'Irroratums' have scarlet flowers, and this tree in full bloom on the knife-edge of the ridge must have been a never-to-be-forgotten sight. The largest leaves I secured were a foot long and six inches wide.

Near the village, beneath a gigantic Oak, I picked up the butter-golden corollas of an epiphytic *Rhododendron*; but the plant was away up out of sight, screened behind the dense foliage. Several times in the course of the next few days I was tantalised by the sight of pools of melted butter, as it were, in the forest, where this species had scattered its flowers, but the plant kept right out of sight, very high up. And then on September 25, I found that one or two epiphytic 'Maddenii' *Rhododendrons*, on which I had had my eye ever since June, were

FIG. 203.—UPPER SEINGHKU VALLEY.
Alpine turf, 12,000 ft. alt.

loads, which had not yet been untied; the servants were lighting a fire. Suddenly, without any warning, I heard one ominous crack, followed by a tearing sound, and one of the coolies gave a shout of fear and astonishment. I needed no second encouragement to do something, so sprang to my feet. With a bound I was through

* The previous articles on Mr. Kingdon Ward's Ninth Expedition in Asia were published in our issues of August 14, 28, October 9 and November 20, 1926, and January 1, February 19, March 5, 19, April 9, 30, June 4, 18, July 30, August 20, September 10, October 1, 15, November 5, and 19, 1927.

this butter-gold species. The flowers are small for a 'Maddeni,' borne in trusses of four to six, scentless, but of so unusual a colour as to proclaim the plant a first-prize-winner. No doubt it is not quite hardy, except in the

which tasted better than they looked. Epiphytic and climbing plants were flowering, amongst the latter being one or two species of *Crawfordia*, and a *Clematis* (including *C. urophylla*, with tottering, cream-coloured flowers), a

in fact, only three trees in the two or three dozen I found had flowered this year, and they were all so smothered with moss, it was clear they were not happy here. The tanglewood did not escape the notice of Shakespeare, for to what else can these lines refer!

The trees, though summer, yet forlorn and lean,

O'ercome with moss and baleful Mistletoe.

In wealthy fruit, *I. nothofagacifolia* must be a wonderful sight. The berries are very small, almost sessile, bright scarlet, and resemble rows of wee beads sewn along the framework of the flat, green, wing-like branches.

By the time we got up to the temperate rain forest—*Quercus*, *Ilex*, *Magnolia mollicomata*, *Rhododendron sino-grande*, etc.—we had our heads well into the clouds, and the usual steady drip, drip, drip, from the vast canopy overhead, made the prevailing gloom even more grim. It was almost dark by the time I reached the alpine meadow; I noticed that all the snow had gone, that the barren earth screes where the packed snow had lingered so late, were covered with a rank growth of herbs, and that the sappy meadow was almost impassable. I was soaking wet, and expected to find a soggy tent pitched at the slope of an aqueous meadow, where every prospect pleases, and only man is vile. Nothing of the sort. The Tibetans had built themselves a fine, new shelter, with a solid bark roof and a bark floor, larger even than the hut at my base camp; so I promptly took possession and lit a fire, and was quite comfortable. *F. Kingdon Ward.*

FIG. 204.—A KACHIN "NAT" ALTAR IN THE HILL JUNGLE, UPPER IRRAWADDY.

mildest districts; we have named it *R. chrysoplepis* (K.W. 7,455). Its fellow epiphyte (K.W. 6,809) growing on the same tree, did not flower while I was there.

By the time we reached my base camp we had run the gauntlet of thousands of famished leeches which were just sitting up and waiting for us, and the almost naked coolies arrived with arms and legs striped like a Bengal tiger; one man was so covered with blood, which streamed down his face, as to be unrecognisable. The meadow had grown waist-high, and it harboured all kinds of loathsome life besides leeches. Our home-coming was quite like our departure. I had cherished a fond hope that by the end of September conditions would be on the mend. Vain delusion! My hut was a sty, full of earwigs, cockroaches and all uncharitableness. It was mouldy, the roof leaked, the floor was littered with leaves, and the wind moaned through the chinks. However, by the time I had lit the fire, things began to mend, although the fire smoked most evilly for the first two days, because the wood was so wet.

Next day the coolies had to depart, as we could not feed them. The girls took half their wages in beads, which were doled out by the chokara who, knowing the exact value of beads to Nung damsels, was much more frugal than I would have been.

Now began the usual tussel with the headman, over coolies. I wanted to go straight back to my alpine camp—there was nothing to do here; and the headman promised coolies day after day, and always it was "to-morrow they shall come, Bimbo." And to-morrow came, and came again, and still I was kicking my heels at the base camp. Finally, exasperated, I became extremely rude, so much so that when, on September 25 the headman arrived with a small deputation singing the usual "to-morrow" chorus, I laid hands on them and pressed them into immediate service, under pain of sudden death. So we started for the upper valley with seven coolies (two of whom were my own servants), taking the barest necessities for a few days' existence, and trusting to the remaining loads following in a day or two; the great thing was to make a beginning.

Down in the valley the Maize was ripe, and mostly gathered in, and I got some Peaches

fine Composite (probably *Senecio*) and other things; the epiphytes were mostly such as I had previously met with. In the meadow grew giant Thistles, fifteen or eighteen feet high, with rather ridiculously small heads of pale yellow flowers; with species of *Umbelliferae*, *Swertia*, *Anemone japonica*, *Campanula colorata* and various grasses.

FIG. 205.—CANE BRIDGE OVER A TRIBUTARY OF THE IRRAWADDY.

When we reached the upper forest things were more interesting. There was nothing much in the undergrowth except a variety of small-flowered *Impatiens*, and a queer, colourless, saprophytic *Orchid*; but I found all the trees and shrubs I was keeping a watch on. The beautiful, small-leaved *Holly* (*Ilex nothofagacifolia*), though not quite so rare as I thought in the tanglewood, had set very few seeds;

NOTICES OF BOOKS.

Plant Pest Control.

As plant pests and diseases, like the poor, are always with us—in spite of the enormous sums expended annually on their destruction—this authoritative volume* on the general subject of pest-fighting measures will be welcome to all horticulturists who have a working know-

ledge of the German language. The work is the eighth volume of a series entitled "Chemie und Technik der Gegenwart" (Present Day Chemistry and Technics). Its nearly 450 pages are closely printed and full of matter; there is no padding, and the information

* *Schädlingbekämpfung* Von Dr. Walther Trappmann. Leipzig: S. Hirzel. Price: paper, RM. 20., bound, RM. 22.

is given in as interesting a form as so technical a subject will permit, the text being clarified and illustrated by a number of excellent diagrams and photographs. The author is well versed in his subject, and holds the important position of Regierungsrat at the State Biological Institute in Dahlem, Berlin. He passes in review the entire field of pest destruction and prevention, and it would be hard to mention a single measure with which he does not deal, at least cursorily. On p. 110 he mentions that, in Holland, bulbs are treated with hot water as a precaution against eel-worm; as is well-known, this treatment, after many experiments, was adopted several years ago in British bulb-growing districts, and has been found eminently successful.

The greater part of the book is naturally occupied with the consideration of the many hundreds of chemical remedies in liquid and other forms. It may, perhaps, be a surprise to some readers to learn that Pliny, the historian, records some early experiments in treating seeds with oil, fat, or pitch, mixed with a decoction of Cypress leaves, to protect them against marauding pests. In the middle ages, crude attempts were made to drive away

mended, as it may be more quickly applied, there is little delay in loading the spraying apparatus, and the necessity of transporting water for diluting the spray material is entirely avoided. Those who have visited some of the steep, terrace vineyards of southern and central Europe will appreciate this last advantage at its true value.

Bird preservation, for the destruction of caterpillars and wireworms, is used on the one hand, and on the other hand, sparrow destruction is dealt with, and the author speaks approvingly of the English "rat and sparrow clubs." Perhaps he does not realise how many friendly and useful insect-eaters are sacrificed in the zealous pursuit of "sparrows" by the younger members of these clubs.

Hydrocyanic acid gas is mentioned as excellent for ridding houses of pests, but the author states that, although much used in Germany for the fumigation of ships, mills, and granaries, the use of this chemical for hot-houses is not now common.

The State organisation of pestology seems to be farther advanced in Germany than in this country, and Dr. Trappmann gives (pp. 413 *et seq.*) an interesting account of the various

development course of root systems more necessary and useful. Vegetable gardening is an intensive process. Water relations, fertility problems, and cultural practices, such as transplanting and cultivation, are ever critical. And, in addition to these considerations, there is the special fact that since some vegetable crops are grown for their foliar parts or their fruits, and others are produced for their roots exclusively, the relative growth and size of top and root are of primary importance.

The authors have covered a wide range of vegetable crops (thirty-two in all), grown under various aerial and soil environments. Root excavations were made and data taken carefully at successive periods of the growing season, beginning at the seedling stages of the plants and ending with their maturity in the case of annuals, while following non-annuals beyond the first year. The valuable results obtained in this work are presented in an attractive, comprehensive and forceful manner. As a supplement, the literature on the question is well reviewed and interwoven. The chapter summaries are excellent. The paragraphs headed "Root System in Relation to Cultural Practices" are especially noteworthy, showing as they do just what may be accomplished through an understanding of the plant's underground parts.

The authors are to be congratulated on their achievement. The book is recommended unreservedly to plant scientists, plant growers, teachers and students of horticulture, in fact, to all who are interested in knowing the plant as a functioning whole in order that they may deal with it more intelligently and profitably. J. W. Crist, Michigan State College.

PUBLIC PARKS AND GARDENS.

THE late ex-Provost Duncanson has bequeathed £3,000 for the improvement of the public park or pleasure ground at Alloa.

BOURNE Urban District Council proposes to purchase three acres for a recreation ground for the hamlet of Dyke, in the Bourne urban district.

BILLINGHAM Council proposes to ask the Newcastle-on-Tyne Electric Supply Co. if it is prepared to lease to them a field at Mill Lane for a recreation ground.

THE Heston and Isleworth (Hounslow) Urban District Council has received the sanction of the Ministry of Health to the purchase of land at Cole Park for an open space.

SEAFORD Urban District Council has resolved to make application for the sanction of the Ministry of Health to the purchase of Seaford Head for a public open space. The purchase price is £16,500.

THE Ministry of Health recently held an inquiry into an application by the Southport Town Council for sanction to borrow £65,500 for the purchase and part development of approximately 750 acres of land in Birkdale and Ainsdale for an open space.

THE Town Council of Warwick is recommended to promote a Bill in Parliament authorising the purchase of St. Nicholas Meadow for conversion into a park or recreation ground.

SIR FRANK SANDERSON, M.P. for Darwen, has offered a piece of land near The Pells, Lewes, Sussex, to the National Playing Fields Association, for use as a playground for children.

THE Ramsbottom (Lancs.) Urban District Council has agreed to purchase Nuttall Hall and five acres of land for pleasure grounds. The purchase price is £2,400.

FIG. 206.—MR. F. KINGDON WARD'S EXPEDITION: SHAN HUTS ON THE HKAMTI PLAIN.

insect pests by various means, including the burning of human hair to cause a disagreeable smell. But it was only at the beginning of the nineteenth century that serious measures began to be taken to compose chemical insecticides with a basis of some material known to be poisonous to insect life.

When dealing with the effects of the various chemicals, the author mentions the fact which has often been noted, that a frequent "by-product" of the application of a remedy is the actual stimulation of the growth of the plant treated. Stimulation, for instance, by hydrocyanic acid gas, a well-known remedy for White Fly in greenhouses, was made the subject of experiments by two professors at Brunswick Botanic Garden last year, who found that the flowering period of certain forced plants could be definitely advanced by the application of this gas. (See *Gard. Chron.*, February 5, 1927, p. 101.)

The question of "spray v. powder" for orchards and vineyards, which has vexed so many growers, is discussed by Dr. Trappmann, and the conclusion reached that, on the whole, liquid spray is preferable for small plantations of fruit trees, vines, etc., as it is simple to control, and the operator may see quite easily when a certain portion of the crop has not been reached by the chemical. For very large areas, however, and especially for places remote from a water supply, the powder form is recom-

departments dealing with the subject. Lack of space forbids details, but this section of the book is by no means the least informative, and should interest entomologists and others concerned in the co-ordination of activities of widely differing kinds, but all designed for the purpose of stamping out plant pests and diseases.

A full bibliography and an excellent index complete the work, which will no doubt find a place on the shelves of those who feel they require up-to-date guidance on a subject, which, unhappily, affects every nurseryman and gardener, no matter what the nature or condition of his produce, or the climate in which he works.

Root Development of Vegetable Crops.

THIS book,* published by Messrs. Weaver and Bruner, the former of whom has taken a leading rôle in root researches during the past two decades, supplies a need long felt by all concerned with the science and production of vegetable crops. Perhaps in no other field is an accurate knowledge of the nature and

MESEMBRYANTHEMUM.

(Continued from page 430).

12.—GLOTTIPHYLLUM, HAW.

9. *G. praepingue*, N. E. Br., in *The Gardeners' Chronicle*, 1922, Vol. LXXI, p. 9 (Fig. 207).—Haworth's characters for this species are:—Leaves of different shapes and lengths—some tongue-shaped with points obliquely recurving—some between semicylindric and tongue-shaped—others narrower, longer and

G. praepingue has long since died out of cultivation, but I believe that a plant recently introduced is specifically identical with that which Haworth described, since it fairly agrees with his description and is entirely different from the plant Salm Dyck and all other authors have mistaken for it. The following is a description of it compiled from four different living specimens:—

Leaves with the pairs more or less obliquely crossing one another, ascending-spreading, straight or curved to one side, $1\frac{1}{2}$ – $3\frac{1}{2}$ inches long, 5–8 lines broad at the middle, 4–5 lines thick, somewhat variable, sometimes parallel sided below and narrowing from above the middle to an acute or subobtuse point, sometimes gradually tapering from the base to an acute or obtuse apex, which is tipped with a short, whitish or brownish mucro or point that often disappears with age, and which I conceive to be the "bristle or short point" of Haworth's description; flat or faintly convex on the face, often with an oblique ridge or keel near the apex of the larger leaf where the flat part ends, caused by the pressure upon it of the opposed leaf in bud; convex on the back and becoming slightly keeled or triangular at the apex of the smaller leaf or sometimes of both leaves of a pair, but in more adult growths the apex of the larger leaf is more or less compressed and keeled, and slightly twisted to one side; substance very soft and pulpy; surface smooth, but under a strong lens seen to be covered with short, linear, raised surface-cells, transverse to

nearly circular in outline, compressed, minutely tuberculate, dark brown.

Mesembryanthemum praepingue, Haw. *Obs.*, p. 179 (1795), *Misc. Nat.*, p. 35, *Syn. Pl. Succ.*, p. 222, and *Rev. Pl. Succ.*, p. 95, excluding the reference to "*M. heterophyllum*, Jackson in Andr. Bot. Rep., t. 540 ?"; not of Salm Dyck nor Berger.

South Africa: Locality unknown, introduced by Masson in 1791, according to Aiton. But the plant above described as probably being the species was sent to Kew Gardens by Miss Wilman as coming from Prince Albert Division. And a plant of it in my own collection was sent to me as having been collected at Klaarstroom, near the Zwartberg Range, in Prince Albert Division, by Mrs. van der Bijl, 3!

Mrs. van der Bijl informs me that she "found few perfect plants as the stock seem to have eaten most of the centres out."

Fig. 207 is drawn from various leaves on the plants described above, of natural size, but the apiculus represented at the apex of the leaves often disappears.

10. *G. apiculatum*, N. E. Br. (Fig. 208).—

Leaves probably about 2 pairs to a growth when resting under natural conditions, but under cultivation 3–4 pairs to a growth, with the pairs placed very obliquely or at right angles to one another, ascending-spreading, and one of each pair usually slightly recurving, mostly $1\frac{1}{2}$ – $2\frac{1}{2}$ inches long, sometimes shorter, 4–7 lines broad and 3–4 lines thick at the base, thence gradually tapering to a subacute apex, which is always tipped with a very short, hard, reddish point or apiculus; flat or faintly convex on the upper side, bluntly keeled down the back at the upper part and there trigonous in transverse section, with the sides convex, microscopically ciliate on the edges and apical part of the keel of the younger pair of leaves, the cilia disappearing with age; substance fleshy; surface smooth, glabrous, with the surface cells not raised into short and minute transverse ridges but microscopically and densely

FIG. 207.—GLOTTIPHYLLUM PRAEPINGUE.
Apical halves of leaves; natural size. Leaf-pairs crossing. Flowers sessile.

without any oblique curve or ridge near the points—others with subulate triangular points and ending in harmless, white bristles or short points—and a few with broad, compressed, subdolabriform, keeled points ending in short, white, bristly hairs, exceedingly fleshy, fat and soft to the touch (on which account I have named it *praepingue*—"very fat"); light green, shining, faintly impunctate, whitish and shining near their inner bases or as if frosted over with exceeding minute papillae, the young leaves minutely ciliate at the edges. Flowers nearly sessile (sessile ex *Rev. Pl. Succ.*, p. 95). Pedicel, if any, exceedingly short, rather angular and smooth. Calyx unequally 4-lobed; all the lobes with membranous edges and ciliate keels, two of them larger than the others, with broad, plain dilated bases, triangular points and slightly membranous edges, the other two shorter, with broad, brownish, reticulated margins. Corolla not so large as that "of my *lingueforme*" (*i. e.*, 21, *G. latum*, N. E. Br.), of long duration; petals, linear-lanceolate, broad, minutely denticulate at the apex, bright yellow, shining. Stamens erect, expanding, yellow. Stigmas 8, plumose. Capsule sessile (*Rev. Pl. Succ.*, p. 95), small, with 8 blunt ridges and a large deep central hollow on the top, 8-celled.

The above characters are as given by Haworth, but arranged differently, and clearly demonstrate that the plant figured by Salm Dyck (*Mes.*, §7, f. 5) as *M. praepingue* cannot be the same as that described by Haworth under this name, there being no mention made nor representation in the figure of the "bristles or short points" (*i. e.*, what is botanically called a mucro or apiculus) at the tips of any of the leaves; the flower is very distinctly pedicellate and the stigmas 10. I have therefore described Salm Dyck's plant as distinct, see 4, *G. subditum*, N. E. Br.

FIG. 208.—GLOTTIPHYLLUM APICULATUM.

Portions of leaves; natural size. Flowers pedicellate.

the leaf, glabrous, light green, pellucid-dotted, sometimes appearing under a lens as if frosted at the basal part. Flowers sessile. Calyx in mature bud about 5 lines in diameter, acutely 2-angled, produced above its union with the ovary into a tube about $1\frac{1}{2}$ line long, 4-lobed above; lobes about 5 lines long, ovate, with membranous margins, two of them acute and acutely keeled on the back, and the keel distinctly ciliate, and two obtuse. Corolla $1\frac{1}{2}$ – $1\frac{3}{4}$ inch in diameter, cup-shaped, expanding in the morning even in dull weather if the temperature is sufficient, but more widely open in bright sunshine; petals 45–50, in two series, all united for about two lines at the base, 11–14 lines long, $\frac{3}{4}$ –line broad, linear, acute, entire, clear yellow on both sides, not shining. Stamens erect, somewhat loose (this may be what Haworth means by "expanding"), entirely yellow. Stigmas 8–10, spreading, 2–lines long, acute, plumose, whitish. Ovary half-superior, 8–10-celled. Capsule when closed 5–7 lines and when expanded 9–11 lines in diameter, with 8–10 valves and cells; valves horizontally spreading, $2\frac{1}{2}$ lines long, pallid, with dark brown, expanding-keels, half as long as the valves and diverging from the base, acute and often very minutely toothed along the top, ending precipitously under the base of a minute terminal, awn-like point or tooth, without marginal wings; cells roofed with rather stiff, brownish cell-wings, and the opening nearly closed by a large, compressed, cream-coloured tubercle. Seeds about $\frac{3}{4}$ line in diameter,

FIG. 209.—GLOTTIPHYLLUM CONCAVUM.

Apical parts of leaves, all from one plant; natural size. Flowers pedicellate.

papulate, as seen under a very strong lens, uniformly grass-green, not at all glaucous and not pellucid-dotted. Pedicel $\frac{1}{2}$ inch long, slightly compressed, 2-edged, 3 lines broad and 2 lines thick, smooth, green. Calyx subequally 4-lobed, green or tinted with purple; lobes about $3\frac{1}{2}$ lines long and 3 lines broad, ovate, obtuse, two of them acutely keeled and with a blunt dorsal point, and two with white membranous margins. Corolla 2– $2\frac{1}{2}$ inches in diameter, expanding in the morning irrespective of sunshine if the temperature is sufficient, closing about 7 p.m.; petals in 1–2 series, ascending-spreading, 10–15 lines long, 1– $1\frac{1}{2}$ line broad, cuneately linear, obtuse and often denticulate at the apex, bright yellow, not shining. Stamens

very numerous, erect, forming a ring, leaving the stigmas exposed to view, 4 lines long; filaments and anthers yellow, the former not bearded. Stigmas 8, 1½–2 lines long, radiately spreading, plumose, light yellow. Ovary slightly convex at the top, 8-celled; placentas on the outer wall or floor of the cells. Fruit not seen.

Oudtshoorn Division: Near Oudtshoorn, Marloth 12187!

Described and Fig. 208 (see p. 449) prepared from a living plant received from Dr. R. Marloth. This species bears some resemblance to *G. praepingue*, but its leaves are of firmer substance, not pellucid-dotted, and its flowers are pedicellate.

11. *G. concavum*, N. E. Br. (Fig. 209, p. 449).—Rootstock bearing a number of crowded growths at the top, on very short divisions scarcely amounting to branches. Leaves 2–3 pairs to a growth, ascending until old, then spreading, 1½–5½ inches long, 4–9 lines broad and 3–5 lines thick at the base, narrow, somewhat semiterete and slightly tapering to an acute or blunt apex, usually somewhat curved or slightly sigmoid, one leaf of a pair concave and the other convex on the face, the concave leaf usually keeled on the back and often slightly twisted; soft and pulpy, smooth, glabrous, grass-green, the older leaves (but not the younger) distinctly pellucid-dotted when held against the light. Pedicel about 9 lines long and 3 lines thick, somewhat semiterete, being slightly flattened on one side and somewhat 2 edged. Calyx in mature bud 6–7 lines in diameter, 4-lobed; lobes 4–6 lines long, more or less keeled and three of the keels minutely ciliate, the outer lobes acute and the inner obtuse, with a dorsal point and broad membranous margins. Corolla 2–2½ inches in diameter, opening in the morning, even in dull, sunless weather at a temperature below 60° Fahr. Petals numerous, free, or nearly so, in two distinct series, 12–16 lines long and 1–1½ line broad, linear, obtuse and scarcely toothed at the apex, bright clear yellow on both sides, not shining. Stamens numerous, collected into a central mass, 6–7 lines long, quite concealing the stigmas, yellow. Stigmas 10, radiating, 1½ line long, plumose, yellowish.

Described and Fig. 209 prepared from a living plant sent to me by Mrs. L. Bolus. This species must be nearly related to *G. angustum*, Haw., but according to Haworth's description of the latter species, it differs by its pedicellate flowers, much smaller corolla and free or nearly free petals. The long and narrow leaves (which, when received, were only 4–6 lines broad, but have now become broader and thicker) concave on the upper side of the longer of each pair, distinguishes this from all others known to me. *N. E. Brown*.

(To be continued.)

COMPENSATION FOR MARKET GARDENERS.

If the gardener is a tenant of a market garden to which the provisions of the Agricultural Holdings Act of 1923 apply, that is, those market gardens which come under the two classes of gardens described in my previous article on this subject, he will be entitled to claim certain privileges with regard to compensation for improvements and the removal of non-permanent fruit trees and bushes, and structural additions to the property and buildings which he has himself erected or acquired.

Dealing in the first place with the question of what compensation he is entitled to claim and for what improvements, the improvements in respect of which compensation is claimable are to be found in the third Schedule to the Act of 1923, and are: (1) planting of standard or other fruit trees permanently set out; (2) planting of fruit bushes permanently set out; (3) planting of Strawberry plants; (4) planting of Asparagus, Rhubarb and other vegetable crops which continue productive for two or more years. With regard to these improvements, the tenant is entitled to claim compensation

for them, even though he has carried them out without notifying his landlord or without first obtaining his consent to them. So long as the holding is a market garden to which the provisions of the Act apply, the tenant will be entitled to claim compensation.

All the above improvements, it will be noticed, are improvements which the market gardener has himself carried out, the words used being in every case "planting of . . ." This still leaves us to deal with those improvements which an incoming tenant has purchased or acquired, and with regard to this latter class, the tenant may claim compensation for them under the provisions of section 48 (i) of the Act. The relevant provisions of this part of the section read as follow: "The right of an incoming tenant to claim compensation in respect of the whole or any part of an improvement which he has purchased may be exercised, although his landlord has not consented in writing to the purchase." Thus, if the improvement has been purchased compensation can still be claimed, whether the tenant has obtained his landlord's written consent to the purchase or not. This provision, when set out in full, seems to be quite clear, and no further explanation would appear to be necessary.

The next part of the section deals with the removal of fixtures and buildings which have been erected by the tenant on his market garden, and we must now turn our attention to this subject. The rights of the tenant with regard to the removal of buildings which he has himself put up are that he can recover every such building that he has at his own cost erected at any time, or any building he has acquired since December 31, 1900, for the purpose of the trade or business of a market garden.

This leaves us only fruit trees and bushes which cannot be said to be permanently set out, to deal with, for, as we have seen, compensation can be claimed for those which are *permanently set out*, these words being employed especially. With regard to fruit trees and bushes which are not so permanently set out, however, section 48 (i) of the Act provides that a tenant may remove all fruit trees and fruit bushes planted by him on the holding and not permanently set out, but if the tenant does not remove such fruit trees and bushes before the termination of his tenancy they shall become and remain the property of the landlord, and the tenant shall not be entitled to any compensation.

So that the tenant although not entitled to compensation, may remove non-permanently set out trees and bushes, provided he does so before the end of his tenancy. It is important that the effect of this section should be known, otherwise the tenant may, through ignorance, find himself less well off than he might have been. *H. Sharman*.

ROADS OF REMEMBRANCE.

ANYTHING more bare and devoid of beauty than the banks of a new arterial road it would be impossible to imagine, especially where excavations or embankments have brought the subsoil to the surface. Feasible schemes to beautify them should have the whole-hearted support of all lovers of the countryside, but it is questionable if the scheme proposed by Richard Rigg (p. 412) comes under this category.

Arterial roads are costly to make and maintain, and would never have been made except for the urgent reason that more space and a better view of the quickly oncoming traffic were necessary. It is hardly likely, then, that those concerned, viz., the Ministry of Transport and the Local Authority will hand over the sides of these roads for the purpose of beautification, unless very responsible guarantees in regard to the work are forthcoming. They would have to consider the obstruction of the view of the road, especially in the case of curves, etc., and the fact that before any successful planting could be done considerable preparation, including much heavy ground work, would be necessary.

There would also be the question of mainten-

ance, for the work once begun should be carried out in good order and protected afterwards. Who is to give these guarantees and be ultimately responsible? The Chairman and Committee of the Roads of Remembrance Association? If so, how are they to control the mixed, voluntary forces that may be at their disposal?

These forces are to consist of persons experienced in planting, leaders of organisations of young people, and the boys and girls themselves, especially "those who live in crowded homes without a garden." (The italics are mine.) In other words, boys and girls who have never handled a spade are to be regarded as specially desirable. The officers may be excellent, but I am afraid that the rank and file will be rather weak for the work. It is too much to ask even young professional gardeners to undertake the heavier ground work in their spare time, but they might be found willing to plant a tree and look after it, especially if it bore a label recording the fact.

Those of us who live close to main roads know full well how thick the traffic is, particularly on Saturdays and holidays; indeed, it is often dangerous for an experienced person to cross the road. Yet it is on these days that children are to be brought out into strange surroundings and dumped on either side of our arterial roads! Can a more fruitful source of accidents be imagined?

When the grass plots have been turned into gardens, and the trees are in bloom or fruit, who is to attend to or protect them? That they would need protection, gardeners and owners of property know only too well. When your correspondent writes of using flowers grown on the roadside to adorn the Cenotaph he is like the dairymaid of old—looking forward to the future with optimism.

There remains the question of how this innovation would be regarded by those whose property adjoins the road. The trees would necessarily be planted close to the fence, for several reasons; first, because of the danger of obstruction to the view of the road, and also because if any natural soil is left it would probably be found near the fence. Trees in such a position would eventually overhang the ground adjoining, and any fruits borne on them would become the owner's property. But hedges under trees are always weak, and what boy could resist passing through to look for fallen fruit? I understand they manage these things better on the Continent; perhaps the boys are more saintly—or less enterprising!

While most of the proposals suggested on p. 412 are impracticable, the suggestions that boys and girls should collect the seeds of suitable wild flowers and sow them on the bare banks is excellent, and would probably be successful. *J. Comber*.

FRUIT GARDEN.

TWO GOOD LATE DESSERT APPLES.

SOME very interesting notes on Apples appeared in your issue of November 19, and I venture to comment on two varieties.

Your correspondent *Market Grower* wisely states that if only we had one or two good late dessert varieties we could compete, throughout the winter, with the imported Apples which now hold undisputed possession of our markets at that time. Later on, he refers to Laxton's Supreme, and I presume this is a slip of the pen for Laxton's Superb.

If market growers want a late variety to compete with the foreigner, surely Laxton's Superb fills the bill. It has only to be tasted to be acclaimed. I detest the usual childish and silly question "Is it better than Cox's?" It is neither better nor worse than Cox's Orange Pippin, but it has a most delicious flavour entirely its own, and it is a worthy follower of that variety. Further, it is a free and consistently annual cropper. I regard it as one of the really great market Apples of the future, especially when the public becomes educated to the fact that a brilliant scarlet skin does not inevitably indicate an Apple that is good to eat. I saw an Apple exhibited at two recent R.H.S. meetings, bright scarlet all over, yet I

would not eat it. Laxton's Superb is not of this type, but is an Apple that one may eat with enjoyment, and when ripe it possesses a warm, mellow colouring, without the brilliancy of some of the "shop-window" sorts.

Another Apple mentioned by *Market Grower* is that nice little Belgian variety, Reinette Rouge Etoilée. I know this Apple well, and having grown it for many years, I can assure your correspondent that it is of very fine flavour and quality, though not, perhaps, in the very front rank. A peculiarity is that it carries its bright red colour right into its flesh in many cases, giving a cut fruit a very appetising appearance.

Salcote Pippin is admirably illustrated in the issue of November 19, p. 411, but no picture can give an idea of its attractive colouring, as those who saw it exhibited at the R.H.S. meeting on October 11 will remember. It is streaked and flushed with yellow and a mellow shade of red, and overlaid here and there with russet. That old Apple grower, Mr. Joseph Cheal, remarked to me that it "had the look of a well-flavoured Apple," and he was right. I feel quite confident there will be an excellent opinion of Salcote Pippin when it is duly introduced to the public. *F. Herbert Chapman.*

VEGETABLE GARDEN.

THE CARDOON.

CARDOONS are not cultivated extensively in this country, but this need not deter anyone from growing them, especially as they make a welcome addition to the vegetable supplies at this time of the year. The blanched stalks of the inner leaves form the edible portion of the plant, as well as the thickened main root, and when cooked to a fine degree of tenderness they have a distinct and agreeable flavour.

They are generally grown in trenches in much the same way as Celery but, naturally, they need more room. Good cultivation throughout is essential, as the slightest check at any period of growth causes bolting and the crops become useless.

If early supplies are required it is customary to sow seeds in heat in March or April and plant out at the end of May or beginning of June. If this practice is followed it is better to sow the seeds singly in small pots so that the plants may be handled easily for hardening off and transferred to their permanent quarters without check. Equally good results may be obtained by sowing seeds in the open trenches in May. If cold nights ensue, the seedlings may be protected by inverted pots, but when established they grow away rapidly and by September make sufficiently large heads for blanching.

Great care should be taken with blanching as unless this is thoroughly done the inherent delicate flavour of the Cardoon is not brought out. The most satisfactory method is to bind soft hay-bands around the plants, after which the soil may be drawn up to and pressed firmly about them. *A. P. C.*

HOME CORRESPONDENCE.

Birds and Fruit.—Do your correspondents under this heading, on page 333 (October 22) realise what would happen if birds were entirely banished from farms, gardens and orchards? Probably not, but if they knew more about the subject and took the trouble to study the evidence in favour of the birds they would quickly change their views. It is the same old tale. The birds are blamed and penalised for the (comparatively) small amount of damage they are seen, or often only believed, to do at times, but the vast amount of good they are doing all the rest of the time is unknown, or wilfully overlooked in order that somebody with a gun may indulge in the Englishman's notorious desire "to go out and kill something." I recommend your correspondents, after they

have read Miss Gardiner's note on p. 412 (November 19), and carefully studied Dr. Collinge's book* (published by Dulau and Co., Ltd., 32, Old Bond Street, W.1., at 2s. 10d., post free) to send 1s. to Miss Gardiner, 82, Victoria Street, S.W.1., for a copy of *Farm, Garden and Birds*, and the leaflet on *Birds, Insects and Crops*, from which they will obtain directions, suggestions and hints from practical growers for the safeguarding of crops and fruit without destruction of bird life. I notice that *T. L.* recommends the use of "Nipper" mouse traps for catching birds, but this kind of trap is one of the most brutal and uncertain traps ever invented. I remember a case, when we used this trap at home, of an unfortunate mouse being caught by one leg and thus spending hours of agony until it was discovered in the morning. A bird might be caught by leg, wing, tail, or even beak, and dangle in the tree for hours before discovery. This trap should be entirely prohibited, as the pole-trap is, and the abominable steel-toothed traps ought also to be. *C. Nicholson.*

—Certainly, so far as concerns this place, a portion of the quotation from Dr. Collinge's work given by Miss Gardiner (*Gard. Chron.*, November 19, p. 412), needs transposing, and should read: "The benefit it confers is comparatively insignificant when compared with the great harm it does." The earlier work of Dr. Collinge, that I have seen, was largely based on the findings of insect remains, etc., in the stomachs; now I venture to think that it would require an almost superhuman observer to recognise the small amount of Pear or Apple in a tit's stomach, which would remain after pecking at the fruits and irretrievably spoiling them; I estimate the amounts taken at about fifty cubic millimetres. Based on this method of observation, let us picture Mr. Richards as an M.F.H. adjudicating poultry claims—he would say, "We have examined the stomachs of all the foxes killed last year, and we have failed to find either cock's combs or duck's eyes; consequently, your claim for ducks and cocks cannot be upheld." I judge by another method, that of damage done—for instance, this year I had a small crop of Doyenné du Comice Pears, perhaps a dozen-and-a-half; they were round about 14 oz. to 15 oz. in weight each, and were bagged up early to protect them. The tits pecked through bag and skin and removed some fifty or sixty centimetres of the pulp from all but one; result, we only had one Pear on the table. Some half the crop of Cox's Orange Pippin was similarly spoiled, though the fruits were bagged. It seems that gauze bags are rather more effective than paper ones, especially than the translucent paper. Not a few yards away is an antique Golden Noble tree, swarming with woolly aphis and all sorts of good insect food (Apple Sucker, Aphis, Lygus, etc.), but these the tits leave practically untouched. I offer a hearty invitation to Mr. Richards to come and study the question in my garden before he again rushes into print on the subject; perhaps he may then be able either to advise me how to get rid of the pest or how to protect my crop. *H. E. Durham.*

—As an amateur grower of British fruits, country bred and on the land all my time, I claim to be able to write about the wholesale destruction the little Blue Tits cause, more especially on the best exhibition fruits. It is no uncommon thing for these birds to spoil from ten to twenty fruits of Apples or Pears in a single day, consequently I have to use muslin bags, which entails time and expense. For myself, I would shoot the last of these destructive creatures, and I am quite sure most fruit growers would do the same. I know full well that every living creature does a certain amount of good, but the harm they do often outweighs the good, ten times over. *J. A. Stidston.*

Superphosphate and Peas.—I should like to point out to Mr. Roy that my note on "The Sowing of Peas" (page 252) was the faithful

* A new edition (1926) of this book in nine parts, at 6s. 3d. each, may also be obtained by those who are sufficiently interested.

record of an experiment. I did not advocate the use of superphosphate as a factor in cultivation—for which Mr. Roy is pleased to make me responsible (page 412). My object was to compare the results of thick versus thin sowing. The warning against the use of superphosphate in the seed drills has no terrors for me, nor need it have any terrors for other gardeners, if their experience should prove to be like my own. The germination in the experiment to which reference was made was excellent. In addition, I am responsible for the cultivation of about fifty rows of Peas each year under the varying conditions of a large county. Superphosphate is used in every drill at seed time, at the rate stated in my note, and I have not heard complaints about bad germination, nor do I detect any evidence of it. On the contrary, I am convinced that the manure operates as a stimulus in the formation of roots, and for that reason I shall continue to recommend the practice. *Geo. H. Copley, N.D.H.*

Unwanted Flowers.—Readers of this paper will have been struck by the inconclusiveness of the result of the *Observer* competition referred to in your issue of November 5 (p. 357), an inconclusiveness to which we are accustomed in the columns of the ordinary Press. Does Sunflower refer to the annual, or to one of the perennials, or to all Sunflowers? I can understand Miss Mellish being unwanted, because with its rampant runners it is a thorough nuisance in a garden. Again, does "Aster" mean China or Comet, or Alpine Aster, or Michaelmas Daisies? I can understand the double China Asters not being wanted! "Geranium," no doubt, means the scarlet (and its varieties), Fancy and Scented Pelargoniums. There are a good many of the true Geraniums which are grown in gardens and are certainly not unwanted. *C. N.*

Foxgloves and Verbascums.—Whatever may be the explanation of the occurrences described by Edward O'Brien in your issue of October 15 (p. 313), he may be quite sure that Foxgloves will not grow from the seeds of Mulleins, or Mulleins from Foxgloves. Had he given some more data, it might have been possible to explain the mystery, and one would like to know (1) what had been grown on the ground where the white Foxgloves first appeared, and what was the nature of the "clearing up"? If it had been long fallow, was it dug at all? Seeds will lie dormant for many years in the ground, to spring up under favourable conditions after the ground has been dug or otherwise disturbed; (2) what did he do with the Verbascum and Foxglove seeds he saved? Did he carefully paper them, and, if so, is it possible that the papers could have got accidentally mixed? It is pretty obvious that the second crop of Foxgloves resulted from seed dropped from the first few plants; but they may have been really part of the same crop as those, but did not germinate in the same year. This is a common occurrence. It is also obvious that Mr. O'Brien sowed the Verbascum seeds in the ground thinking they were Foxglove, and by some means sowed Foxglove seeds in the box—if it really was Foxglove; young Foxglove seedlings are very like the young seedlings of some Mulleins. Does Mr. O'Brien know what species the Verbascum was? Had he seeds of any other Verbascum by him at the time? I think there is no doubt whatever that the seeds were by some means interchanged, and if Mr. O'Brien will very carefully go over the circumstances he will, I am sure, find out where the hitch is. *C. Nicholson.*

Melaleuca hypericifolia.—An error has somehow crept into my note on *Melaleuca hypericifolia* (p. 363), as the sentence which begins at the foot of column two, viz., "Three years ago," should have read "Three years later," i.e., the plants were finally planted out four years ago and only flowered a year past, in October, for the first time. *A. T. Harrison.*

Papaver umbrosum.—*Papaver umbrosum* seems to be of wayward habit. I had some seeds in 1914 which were scattered about on different sites. In 1917, one plant, the first, appeared;

from this seeds were obtained, and scattered in numbers. In 1919, three plants appeared, and from them some of the seeds afforded about ten seedlings, which were transplanted, and made a fine show. Most of their seeds were allowed to sow themselves, and this autumn a single plant has appeared which looks as if it would confirm the idea that it is true to type. Its rich crimson-scarlet and black blotches make it a very effective ornament—when it is pleased to appear. *H. E. Durham.*

United Horticultural Benefit and Provident Society.—May I, through your columns, draw attention of young gardeners to the great advantages of membership of the United Horticultural Benevolent and Provident Society? Since the war, many young men have joined the ranks of the gardening profession, and a large percentage of them, no doubt, belong to one or other of the many well-known friendly societies. Yet the membership of the U.H.B.P.S. does not increase from year to year in anything like the proportion the officers and old members desire. It is only right and prudent that every working man, nowadays, should be a member of an approved society, but why, in the case of gardeners and nursery employees, do they ever look beyond this, our own, organisation? I think I may safely state, without fear of contradiction, that no other society in our country offers such unique benefits and advantages as this one, and, what is more to the point, it is in every respect soundly and economically managed by those responsible for its members' interests. Added to this, the National Health section of the Society's business is conducted in a prompt and exemplary manner; in short, the U.H.B.P.S. offers all the benefits of the popular friendly societies, and much more, with none of the drawbacks; and above all, it is the gardeners' own society. Personally, of course, I have no axe to grind, but as an old and satisfied member, it grieves me to find young men joining other societies to the exclusion of the one to which they should be proud to belong. If any young gardener is not fully cognizant of the aims and benefits of the U.H.B.P.S. he should write to the genial Secretary, Mr. A. C. Hill, Alexandra Road, West Kensington Park, London, W. He will, I am sure, obtain all the information he needs to persuade him of the wisdom of becoming a member. *Joseph E. Palmer, Tilstone Gardens, Tarporley, Cheshire.*

The R.H.S. Fruit Show.—In your issue of November 5, page 372, *Exhibitor* wrote regarding the inaction of the R.H.S. on certain matters, and up to now no one has made any comment on his charges. The reason, I presume, is that he did not sign his proper name. If he will do so, no doubt he will get the opinion of other exhibitors. *Exhibitor No. 2.*

Apple Cornish Gilliflower.—In your issue of the 26th inst., under the heading "Apple Cornish Gilliflower," page 430, a correspondent repeats the observation made many years ago by Dr. Hogg in his *Fruit Manual* that this Apple should be pruned with great care as it bears its fruit on the tips of the branches. Last year, I summer pruned my bush trees in the manner recommended by Mons. Lorette, viz., all the laterals when the thickness of a pencil were cut back to the base, leaving a stump not more than one-quarter-of-an-inch long. This year, I had a plentiful crop of fruits, the Apples, two and three together, sprang in a remarkable and curious way from the surfaces of the stumps. It was difficult to see or imagine where the blossom could have been. In addition to the fruit, the stumps developed fresh fruit- and growth-buds. Altogether a most satisfactory result. Your correspondent's description of the Apple, if I may say so, hardly does it justice. It is a handsome fruit and its colour is predominantly red. Dr. Hogg describes it as "brownish-red, streaked with brighter red on the side next the sun." He also classes it as large. The Cornish Gilliflower is, I believe, considered a shy bearer; can this old superstition about the pruning be in any way responsible? *R. R. H. Moore, Painswick Lodge, Cheltenham.*

SOCIETIES.

ROYAL HORTICULTURAL.

NOVEMBER 29.—There was quite a bright show in the Royal Horticultural Hall, Westminster, on this date, when the Society held its customary fortnightly meeting. Chrysanthemums were the principal floral feature, and these flowers were shown in quantity and of very good quality. There was also a very attractive group of winter-flowering Begonias, and Carnations were displayed in the accustomed quantity. Several collections of Orchids, a handsome display of Apples, various garden sundries and collections of paintings and drawings of flowers and garden scenes all helped to fill the hall. The weather was wet and dismal, and consequently the attendance was rather small.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Mr. Gurney Wilson (Hon. Sec.), Mr. C. J. Lucas, Mr. Frederick J. Hanbury, Mr. Sidney Flory, Mr. Fred. K. Sander, Mr. J. E. Shill, Mr. H. G. Alexander, Mr. John C. Cowan, Mr. T. Armstrong, Mr. A. McBean, Mr. E. R. Ashton, Mr. J. Wilson Potter, and Mr. Charles H. Curtis.

FIRST-CLASS CERTIFICATES.

Miltonia William Pitt, Dell Park variety.—A wonderful Orchid. The large flowers are of rich and bright velvety-crimson colour, while the white-edged, scalloped mask is of brownish hue, with crimson radiations extending into the white area. This is an outstanding variety of a splendid hybrid. Shown by BARON BRUNO SCHRÖDER (gr. Mr. Shill), Dell Park, Englefield Green.

Calanthe Hexham Lad var. Richard (Burfordiense × Angela).—A brilliant variety with bold flowers. There are two white or pale rose marks at the base of the crimson lip, and the spreading sepals are deep rose-red, while the petals are ruby-crimson. A most attractive *Calanthe*. Shown by CLIVE COOKSON, Esq. (gr. Mr. Stables), Nether Warden, Hexham.

AWARDS OF MERIT.

Calanthe Hexham Gem (var. 4.B.) (Angela × Bryan).—A pretty hybrid with pure white lip, sepals and petals, and deep crimson blotch at the extreme base of the lip. A lovely *Calanthe*. Unfortunately a varietal name was not given to this seedling. Shown by CLIVE COOKSON, Esq.

Cymbidium Lucaste (grandiflorum × Warbler).—A pleasing hybrid with a large, greenish-white, brown-spotted lip that betrays its descent from *C. grandiflorum*. The sepals and petals are clear, pale ivory-green. Shown by W. J. BURSTOW, Esq., Old Quarry, Haywards Heath, Sussex.

Odontioda Pierre Loti (Coronation × Royal Gem).—In this pleasing hybrid the broad, rounded flowers are rosy-mauve, with wide, deep rose margins to the petals, and narrow rose margins to the sepals. Both sepals and petals have several deep rose-red spots of various sizes. The lip carries one rose-red spot and the disk is yellow. The plant shown carried a spike of eight fine flowers. Shown by J. J. BOLTON, Esq. (gr. Mr. Lyne), Claygate Lodge, Claygate.

GROUPS.

CLIVE COOKSON, Esq. (gr. Mr. Stables), Nether Warden, Hexham, showed a series of interesting *Calanthe* hybrids, principally derived from crossing *C. Angela* with *C. Bryan*. One was pure white with a crimson mark at the extreme base of the lip, while another variety had brilliant ruby-crimson colouring; between these there were many gradations of shade and colour. A special vote of thanks was accorded.

Some lovely *Odontoglossums* and *Odontiodas* were shown by Messrs. CHARLES WORTH AND Co., together with *Laelio-Cattleya Istria*, the fine *Cattleya Wolsteriana*, *Miltonia Hyeana* with six flowers; *Brasso-Cattleya Massangeana* and numerous *Cypripediums*. A small group submitted by Mr. HARRY DIXON included *Cypripedium insigne Sanderae*, *Cymbidium*

Doreen, *C. erythrostylum* var. *Winnianum*, *Masdevallia tovarensis* and several *Odontiodas* and *Odontoglossums*.

Messrs. SANDERS' group included numerous examples of *Vanda coerulea*, a specimen of the rare *V. Kimballiana*, *Odontoglossum grande* in fine form, *Cymbidium Caer Brito*, *Cypripedium Our Prince*—very fine—*C. Merope*, *C. Minotaur* and *Odontoglossum Isabel*. This was a capital display for the time of year. *Laelio-Cattleya Purple King* and *L.-C. Schrödera*, the latter carrying a six-flowered spike, were shown by Messrs. ARMSTRONG AND BROWN.

Messrs. STUART LOW AND Co. had a very bright exhibit containing *Laelio-Cattleya Nella*, *L.-C. Luminosa aurea*, *Sophro-Cattleya Pearl*, *S.-C. Queen Empress*, the fine old *Dendrobium thrysiflorum*, the curious, pendulous *Cymbidium elegans*, *Odontioda brugensis*, *Lycaste Tunstallii*, and several good *Cypripediums*. *Laelio-Cattleya Senator*, *L.-C. H. T. Pitt*, *L.-C. Edzell* and such bold *Cypripediums* as *C. Bisham* in variety, *C. Atlantis*, *C. Ardestrie* and *C. Cardinal Mercier* were shown by Messrs. BLACK AND FLORY.

Floral Committee.

Present: Section A.—Mr. Henry B. May (in the chair), Mr. J. F. McLeod, Mr. Arthur Turner, Mrs. Ethel M. Wightman, Lady Beatrix Stanley, Mr. H. J. Jones, Mr. J. M. Bridgeford, Mr. M. C. Allwood, Mr. James B. Riding, Mr. R. Findlay, Mr. W. B. Gingell, Mr. J. T. West, Mr. D. B. Crane, Mrs. Helen L. Smith, Mr. Charles E. Pearson, Mr. G. W. Leak, Mr. E. R. Janes, Mr. D. Ingamells and Mr. W. D. Cartwright (Secretary).

Section B.—Mr. Gerald E. Loder (in the chair), Mr. W. J. Bean, Mr. E. A. Bowles, Mr. G. Reuthe, Mr. C. Williams, Mr. Charles T. Musgrave, Sir William Lawrence, Bt., Mr. R. C. Notcutt, Mr. F. G. Preston, Mr. E. H. Wilding, Mr. W. B. Cranfield, Mr. L. R. Russell, Mr. Mark Fenwick, Mr. T. Hay, Mr. C. J. Lucas and Mr. N. K. Gould (Secretary).

AWARDS OF MERIT.

Carnation Canadian Pink.—A well-formed flower, borne on long, erect stalks and of more than average size. The substantial petals are lightly serrated. The colour is a glowing light pink.

Carnation Wivelsfield Claret Improved.—As the name suggests, this is an improved form of the well-known variety. The flowers are larger and of brighter colouring than those of the older variety. Both were shown by Messrs. ALLWOOD BROS.

Carnation Melchet Beauty.—This Fancy *Carnation* has been shown frequently of late, and in consistently good form. The flowers are large and fragrant, and the substantial petals are fringed. The colour is dull chocolate, striped with lines of deep vermillion. Shown by Messrs. STUART LOW AND Co.

Chrysanthemum Gaiety.—A splendid Single of enlarged *Mensa* type. The ray florets are of rich crimson-chestnut colour, and the flowers have a narrow golden zone and a small disk. Shown by Mr. H. SHOESMITH, junr.

Chrysanthemum Mrs. E. Page.—This is a delicately beautiful Single of rather more than medium size. There are several rows of golden yellow florets which are shaded with chestnut towards their tips. Shown by Mr. H. WOOLMAN.

Chrysanthemum Tom Abbott.—A magnificent Japanese variety of the best exhibition size and form. The flowers measure fully eight inches across and are equally as deep. The broad, pointed florets are of bright canary-yellow colour. A few of the older florets at the base of the flower are lightly stained with peach-pink. Shown by Mr. H. J. JONES.

CULTURAL COMMENDATION.

Protea mellifera.—A very good specimen of the Honey-bearing *Protea* was shown. By some means this robust, erect shrub, many years ago received the specific name of *repens*, but the obvious misnomer was corrected long since. The illustration in the *Botanical Magazine*,

t. 346, dated October 1, 1796, gives an excellent impression of the stout stem, narrow, sage-green leaves, and large, terminal flower with its fleshy, rose-tipped, greenish scales which enclose the florets. Shown by Sir WILLIAM LAWRENCE, Bt., Burford, Dorking.

GROUPS.

Chrysanthemums occupied the major portion of the space devoted to the exhibits of plants and flowers. At the end of the hall Messrs. SUTTON AND SONS arranged a large collection of plants most attractively on a mossy bank. These plants were from seeds sown during February of this year. They illustrated their "Autumn Mixed," "Round-petalled," "Dwarf Mixed," and "Star" types. As may be expected, the flowers were almost solely of the Single section of Chrysanthemums, though the Dwarf Mixed strain yielded a few semi-doubles. This large collection made a very attractive display, and fully illustrated the usefulness of seedling Chrysanthemums for general decorative purposes.

On the tabling, Messrs. KEITH LUXFORD AND Co. set up a very fine collection of cut Chrysanthemums. There were several good seedlings of the exhibition Japanese type, and the named sorts included Thos. W. Pockett, pink; Andania, bright chestnut; Geraldine, golden buff; and Louisa Pockett, white. Amongst the many Singles we especially noted Challenger, red-terra-cotta; Mrs. J. Barrrell, golden-yellow shading to terra-cotta; Chestnut Glory, pale golden-chestnut; and Pink Beauty. There was also a large vase of attractive Anemone-centred seedlings.

A valuable collection of cut Chrysanthemums of first-rate market type was arranged by Mr. A. G. VINTEN. The Japanese varieties included Enton Beauty, rich crimson; Miss Ada Booker, bright chestnut; Balcombe Beauty, glowing yellow; Mrs. S. Dove, pink, and Ivy Gay, blush-pink. The chief Singles were Bridgewater, Absolute, Crimson Dawn, Balcombe Gem and Phyllis Cooper.

In their collection of Chrysanthemums, Messrs. W. WELLS AND Co. had good vases of Wm. Rigby, yellow; Majestic, light chestnut; Queen Mary, white, and Helena Margerison, of the exhibition Japanese varieties, and they also staged useful Singles.

A very tastefully-arranged group of winter-flowering Begonias was exhibited by BARON BRUNO SCHRODER (gr. Mr. E. J. Henderson), Dell Park, Englefield Green. In the centre there was a large basket filled with plants of the bronze-leaved Mrs. J. Petersen, while hanging baskets contained equally good plants of Mrs. Leopold de Rothschild. Along the back there was a quantity of Gloire de Lorraine, and in the foreground groups of Elatior of glowing colour, and of Exquisite. Mr. ARTHUR SHAMBROOK displayed an excellent collection of greenhouse Cyclamens in many colours. The plants were of useful, decorative size and the large flowers retained the charm of perfect shape.

Carnations were shown in very good quality by several growers, and by H. C. WALROND, Esq. (gr. Mr. D. Mitchell), Burton Grange, Cheshunt, who had highly creditable vases of Topsy, Laddie, Red Laddie and Maine Sunshine. In their collection, Messrs. ALLWOOD BROS. gave prominence to the varieties Maud Allwood and Cattleya Mauve, which received Awards of Merit at the previous meeting. They also had attractive vases of Topsy, Red Laddie and other older varieties. In another part of the hall Messrs. ALLWOOD BROS. made a pretty "garden" of Dianthus Allwoodii varieties. The plants which had evidently been grown under cool conditions, were very sturdy, and bore plenty of attractive flowers. The recent varieties included an improved Barbara of dark ruby shade; Tony, velvety crimson; Pat, deep rose-pink, and Molly, purple with deep crimson-lake bars.

In their collection of Carnations, Messrs. C. ENGELMANN, LTD., staged bright vases of Laddie, Red Laddie, Maine Sunshine, Rouge, Dorcas, Saffron and other sorts, while Messrs. STUART LOW AND Co. had good vases of the richly

coloured Master Michael Stoop, Philip Sassoon, Brilliant and Spectrum.

In a floor group by the gallery, Messrs. L. R. RUSSELL, LTD., showed berried and foliage shrubs, including Skimmia japonica, Eurya latifolia variegata, Griselinia macrophylla variegata and several varieties of Euonymus. On the tabling, Messrs. WM. WOOD AND SON had well-fruited examples of Skimmia japonica, Coton-easter frigida Vicarii and Pernettya mucronata varieties, with Berberises and other shrubs. Mr. JOHN KLINKERT showed good topiary specimens in evergreen Box.

A pleasant little rock garden was made by Mr. F. G. WOOD, in which he displayed dwarf Conifers, including compact, little specimens of the golden-tipped Cupressus plumosa nana compressa. The Misses HOPKINS also had a small rock garden.

Many vases of sweet Violets were shown by Mr. J. J. KETTLE and Mr. BALDWIN PINNEY. The chief variety was Princess Mary, which was represented by many very good flowers.

There were various exhibits of garden sundries, including a motor-driven Ateo lawn-mower, garden tools from Mr. RICHARD MELHUISE, Winter-washes shown by the BRITON FERRY CHEMICAL Co., the Chase Alpine Plant Protectors, the "Legilab" and "Helichrysa" plant labels, Radium Fertiliser, the Rolcut Secateur and the Ideal Britannia boiler.

Fruit and Vegetable Committee.

Present: Mr. C. G. A. Nix (in the chair), Mr. Joseph Cheal, Mr. P. C. M. Veitch, Mr. George F. Tinley, Mr. A. W. Metcalfe, Mr. A. Bullock, Mr. J. Wilson, Mr. F. Jordan, Mr. H. Prince, Mr. A. Poupert, Mr. W. H. Divers, Mr. E. A. Bunyard, Mr. E. Beckett, Mr. H. V. Taylor and Mr. A. N. Rawes (Secretary).

GROUPS.

A wonderful collection of Apples interspersed with dishes of Pears and bunches of well-grown Grapes, exhibited by the Hon. VICARY GIBBS, Aldenham House, Elstree (gr. Mr. E. Beckett), was the centre of attraction for fruit enthusiasts. The exhibit consisted of some 140 dishes, arranged and staged with Mr. E. Beckett's usual skill, and with the fruits set off by discreetly placed ornamental plants and berries, made a most attractive display. The bright colouring of the Apples was enhanced by the artificial lighting in the hall. The bunches of Grapes, of the varieties Muscat of Alexandria, Cooper's Black, Gros Maroc, Appley Towers, Alnwick Seedling and Alicante appeared particularly fine for the time of the year. Many of the Apples exhibited were varieties seldom met with by the average grower and added interest to the collection. There were fine specimens of the old Rymer Pippin Apple and of Crawley Pippin, Pomeroy, Broad Eye Pippin, Buzzar and Black Prince. The most highly coloured Apples noted were Newton Wonder, Cox's Orange Pippin, Emperor Alexander, James Grieve, Gascoyne's Scarlet, Paroquet, Forge and the old Duchess's Favourite. All were of high exhibition quality. The notable Pears were Catillac, Josephine de Malines, Beurré de Jonghe and the little grown Dr. Frouceau. Altogether, this exhibit compared very favourably with any similar exhibit—and was more tastefully staged than most—of recent years.

OTHER EXHIBITS.

The Committee considered a seedling Apple received from Mr. A. C. BATCHELOR, 14, Southern Avenue, Leigh-on-Sea. This was a medium-sized, highly-coloured fruit, something after the style of the old Barnack Beauty. It was no advance upon existing varieties.

Mr. W. H. DIVERS, V.M.H., of Westdean, Hook, Surbiton, brought two Apples for comparison—King of the Pippins and Golden Winter Pearmain. Mr. Divers explained that these two Apples are mixed in the trade, being generally known under the name of King of the Pippins. The broad, open eye of Golden Winter Pearmain serves to distinguish that variety from the true King of the Pippins, the eye of which is smaller and nearly closed. It was also pointed

out that the King of the Pippins described by Hogg is not the variety now grown under that name.

HITCHIN CHRYSANTHEMUM.

THE twenty-fifth annual exhibition of Chrysanthemums, fruit and vegetables was held at the Town Hall, on Thursday, November 10. The day was fine, and during the afternoon there was a record attendance.

The number of entries reached the grand total of 370, which was sixty more than last year. In all classes the exhibits were of excellent quality, and particularly so in the classes for vegetables and fruits. The large blooms and Chrysanthemums were not quite up to the standard of previous years, but the display, on the whole, was considered good for the season. Table decorations were a feature of the show, and here Mrs. W. G. P. CLARK, wife of the Secretary, won the first prize with the Chrysanthemum Flavia, and her daughter the second prize with Red Dragon.

A new class was provided for an arrangement on a given space, with no restriction as to the number of flowers so long as they represented not fewer than four different types of Chrysanthemums. There were two competitors, and the Silver Cup was awarded to E. MARTIN SMITH, Esq. (gr. Mr. Miller), while Mr. W. G. P. CLARK was second.

The principal class was for six vases of Japanese blooms, distinct, three blooms of one variety in each vase. There were three competitors, and the Silver Challenge Cup was awarded to the MARQUIS OF SALISBURY, Hatfield (gr. Mr. R. W. Hall), for fine specimens of Mrs. A. W. Holden, Mrs. B. Carpenter, Wm. Rigby and others; second, Mrs. HANSCOMBE, Pirton Hall (gr. Mr. Wm. Sherriffs); third, Sir HENRY WHITEHEAD (gr. Mr. C. Carter); in this third prize exhibit a fine R. C. Pulling was the best bloom in the show.

For four vases of Japanese varieties, three blooms of each, another Silver Cup was offered as first prize, and this was won by R. O. OLDHAM, Esq. (gr. Mr. J. F. Kellaway). For six Japanese blooms, distinct, E. MARTIN SMITH, Esq., led and the MARQUIS OF SALISBURY was placed second. The first-prize-winner in this class was also first for six Single Chrysanthemums, and for six Decorative varieties, while for three white Japanese blooms the MARQUIS OF SALISBURY led, and was awarded first prize for a large vase of Japanese blooms, arranged with foliage. Sir HENRY WHITEHEAD was placed first for three coloured blooms.

Fruits were well shown, and the Challenge Cup was won by Major J. F. HARRISON (gr. Mr. A. J. Hartless), with a collection which included Grapes, Melons, Apples and Pears. Mrs. CARL HOLMES, The Node, Welwyn (gr. Mr. Penton), showed the best collection of Apples, and also led for three dishes of Pears. The first prize Muscat of Alexandria Grapes came from E. MARTIN SMITH, Esq., while Sir HENRY WHITEHEAD was first for black Grapes.

In the special class provided by Messrs. James Carter and Co., for a collection of nine kinds of vegetables, there were three keen competitors. Major HARRISON won the Challenge Cup for the third time in succession and it now becomes his property; second Sir HENRY WHITEHEAD; third, E. MARTIN SMITH, Esq.

Major HARRISON also won the leading award offered for a collection of vegetables by Messrs. Sutton and Sons, second and third positions falling to the same competitors as in the above class.

Mrs. CARL HOLMES was awarded first prize for Potatoes, for Leeks, and for Parsnips, while Major HARRISON and E. MARTIN SMITH, Esq., were equally successful exhibitors in other single dish classes of vegetables. The most successful exhibitors in the amateur and single-handed gardeners' classes were Messrs. B. FRANKLIN, W. G. WILLMOTT, and W. G. P. CLARK, for flowers; and Mr. W. MUDDLE and Mr. J. SPRIGGS, for vegetables.

Messrs. KEITH LUXFORD AND Co. arranged a bold display of Chrysanthemums which was greatly appreciated by the Society and admired by the visitors.

SALISBURY AND DISTRICT GARDENERS'.

THIS Society, one of the largest and most enthusiastic bodies of gardeners in south-west England, recently celebrated its twenty-first birthday. Mr. W. F. Gullick, Salisbury, has filled the office of Secretary during the whole period.

Fortunately, lectures are a feature, and on Wednesday, November 23, the large room at the White Hart Hotel was crowded with an appreciative audience to hear Miss Barbara Gullick, B.Sc., deliver a lecture on "Some Notes on British Wild Flowers." Miss Gullick, who is a very clever British botanist, took her listeners in thought to various parts of the British Isles, Wiltshire and the Downs in particular, which she has explored most minutely, in her search for rare and uncommon wild plants. The terms "Casuals," "Colonists," and "Aliens," were explained in a most interesting manner, and she urged the audience to do all they could to preserve the flora of the British Isles, which is one of the most varied and beautiful in the world.

At the close of the lecture questions were answered by Miss Gullick. On the proposal of Miss E. J. Hardy, who mentioned how indebted the Society was to Miss Gullick for her fascinating lecture, seconded by Mrs. A. E. Davis, a very hearty vote of thanks was accorded the lecturer. Mr. A. C. Jonas, who has been Vice-President of the Society since its inauguration, occupied the chair.

Splendid exhibits of Cypripediums from Mr. W. ASHER, Cyclamens from Mr. A. J. HOOPER, and a magnificent collection of Chrysanthemums from Mr. ROBERT BUSH, grower to Mr. Gullick, were on view. The quality of the plants in each instance was so good that a Certificate of Merit was unanimously voted to the respective growers.

READING AND DISTRICT GARDENERS'.

"TUBEROUS Begonias from Seeds and Tubers," was the subject of a lecture delivered in a most practical manner before a large attendance of members at the fortnightly meeting held on Monday, November 21, at the Abbey Hall, by Mr. J. Wynn, The Gardens, Hammonds, Checkenden. The lecturer referred to the double Begonia as a good plant for flowering in the greenhouse during the summer. Although there were various types, double Begonias were his favourites and the only kind grown at Hammonds. After giving many interesting facts regarding the development of the Begonia, Mr. Wynn dealt with cultivation, both from seeds and tubers; composts, watering, temperatures, manuring, etc., and concluded with reference to the Begonia mite.

A lengthy and animated discussion followed, sustained by Messrs. Gower, Townsend, Young, Cook, Beaumont, Carpenter, Reeves, Cox, Howlett and Waite. At the conclusion, a hearty vote of thanks was accorded to the lecturer. A feature of the meeting was the wonderful display of Apples in the competition for three dishes of Apples, three distinct varieties (two culinary and one dessert), no fewer than seventeen lots being staged—a record number of entries in any competition held by the Association. The fruits were in perfect condition, of good quality and excellent in colour, and the judges had great difficulty in selecting the finest set. The awards were as follow: First, Mr. A. W. GOWER, The Gardens, Calcot Grange; second, Mr. T. BUTCHER, The Gardens, Glebelands, Wokingham; third, Mr. C. W. WRIGHT, The Gardens, Beenham Lodge, Beenham. In a class for three dishes of Pears, the first prize was awarded to Mr. F. G. RABBETTS, The Gardens, Bulmershe Court, Reading, and the third to Mr. J. WYNN.

In the non-competitive section, a First-Class Certificate was awarded to Mr. W. BROOMFIELD, The Gardens, Cliffe House, Mapledurham, for a beautiful plant of *Odontoglossum Plump-tonense*. Mr. C. J. HOWLETT, The Mews, Earley, showed ten dishes of well-coloured Apples; Mr. F. G. RABBETTS sent three vases of Roses cut from the open; Mr. H. WADE, The Gardens, Mortimer House, showed Tomatos; and Mr. G. BURCHELL, Earley, Potatos.

DUNDEE HORTICULTURAL.

THE November meeting of the Dundee Horticultural Society was held in the Training College, Park Place, Dundee, when the lecturer for the evening was Mr. W. A. Crichton, C.C.H. (Edin.), of Messrs. Storrie and Storrie, Glencarse Nurseries. Mr. Crichton chose for his subject "Fruit Culture under Glass in Pots," and discussed the advantages of growing fruits in pots under glass as against planting out in borders. He emphasised the fact that later varieties of Apples and Pears which could not be grown successfully out-of-doors in Scotland, could be grown indoors to a perfection beyond the comprehension of many cultivators. Fruits grown in this way were never at the mercy of the very erratic climate which prevails, and the quality was as good as that produced in the south of England. On the motion of Mr. Robert Stewart, the lecturer was accorded a very hearty vote of thanks. Mr. Martin Taylor showed a very fine specimen plant of *Begonia Gloire de Lorraine*, which was awarded a Cultural Certificate.

GUILDFORD AND DISTRICT GARDENERS'.

THE annual meeting of this Association was held on Thursday, November 10. There was a very good attendance, when Mr. Alderman W. T. Patrick, J.P., the President, opened the proceedings by submitting the report of the Committee and Statement of Accounts. Mr. Patrick's review was very encouraging. He congratulated the Association on the success which had attended the activities of each sub-committee, and expressed the opinion that but few provincial horticultural societies could present such a satisfactory statement. Thanks were tendered to the many friends and associates by whose help the summer show had been made so great a success, special mention being made of Lieut. Imms and Mr. Kinggett in this connection, and to Mr. Norman Nation, the Hon. Treasurer, Mr. E. Sawyer, the Hon. General Secretary, and Mr. Childs, for his painstaking work in arranging the lectures and visits to gardens in the district.

Dealing with finance, the report showed credit balances of £23 3s. 8d. in the show account; £5 3s. 3d. in the lecture and outing accounts; and £12 9s. 9d. in the Trading account. The monthly journal account was the only one showing a deficiency—£76 4s. 1d. But a set-off against this is the service rendered to the Association by the free distribution to members of this monthly publication. The *Journal* gives all information and announcements of the various activities, thereby saving the monthly printing and posting of circulars to over a thousand addresses. The general account showed a balance in hand of £49 0s. 1d. at the close of the year.

Mr. Patrick, Mr. Norman Nation and Mr. E. Sawyer were re-elected to the respective offices of President, Hon. Treasurer and Hon. General Secretary, while Mr. W. F. Binfield, Mr. A. Blake, Mr. G. Earl, Mr. King, Mr. J. A. Kirkwood, Mr. H. J. Blunden, Mr. T. Newman, Mr. A. E. Tylecote, Mr. G. T. Watson, Mr. O. Wells, Mr. T. Williams and Mr. A. H. White were appointed to serve on the Committee.

The date of the next summer show has been fixed for Wednesday, July 11, 1928.

For the first lecture of the season, the Association was favoured with a visit by Mr. Lavender, of Messrs. J. Carter and Co., Raynes Park, who gave an address on "Rhododendrons." The topic was treated in an interesting and exhaustive manner, and it was claimed that from a garden point of view Rhododendrons (which now embrace all plants known as Azaleas, including *Azalea mollis*), include some of the most beautiful and ornamental plants grown. They have the advantage of being, for the most part, presentable evergreen plants, and among the best flowering plants, combining handsome foliage, profusion and beauty of flower, and, in many cases, delicious fragrance. By a careful selection

of species and varieties the flowering season may be spread over the greater part of the year. Mr. Lavender stated that the Rhododendron was introduced into England in 1763, but it is within the last half-century that the family has attained its present popularity. He went on to discuss the natural distribution and habit of the plant, methods of cultivation, propagation by seeds, cuttings, layers and grafting, and followed this with information concerning the most suitable sorts to grow, making it clear that in small gardens, and in pots, much greater use might be made of these subjects. While a peaty soil was ideal, it was not an actual necessity, as Rhododendrons will thrive in a well-drained, light, sandy loam, rich in humus, but lacking in lime. An annual top-dressing of about three inches of rotten leaves in spring was recommended to provide cool shelter for the roots.

Mr. Patrick, the President, heartily thanked Mr. Lavender for his lecture.

A few members brought exhibits from their gardens—a collection of vegetables, a bowl of Roses and several plates of Apples—and these were sold for the benefit of the funds of the Association.

CORBRIDGE-ON-TYNE CHRYSANTHEMUM.

THE twenty-fourth annual exhibition was held in the Town Hall, Corbridge-on-Tyne, on November 19. There was a grand display of cut flowers and a very keen competition. In addition to the floral displays some remarkable collections of vegetables were exhibited and proved an attractive feature in a district where vegetables are extensively grown, especially by amateurs, for the local shows.

In the class for four varieties of Japanese Chrysanthemums, in four vases, the DOWAGER LADY ALLENDALE (gr. Mr. J. Thomas), Bywall Hall, was placed first with grand blooms of Majestic, Mrs. R. C. Pulling, Francis Jolliffe and Lord Stewart; second, J. C. STRAKER, Esq. (gr. Mr. A. Hay), Stagshaw House, with Golden Champion, Mrs. Algernon Davis, Majestic and Francis Jolliffe; third, J. DOVE, Esq. (gr. Mr. L. Sharp), Oaklands, Riding Mill. For six Japanese blooms, in not fewer than two varieties, S. E. TULLEY, Esq. (gr. Mr. Macombie), Newton Hall, Stocksfield, led with very fine examples of Queen Mary, Princess Mary and Majestic; second, the DOWAGER LADY ALLENDALE, with Francis Jolliffe and Mrs. T. W. Pockett. In the class for three Japanese blooms, in not fewer than two varieties, S. E. TULLEY, Esq., was again placed first; and A. F. RIDLEY, Esq. (gr. Mr. W. Clayton), Park End, Wark, second.

For three white Japanese blooms, one variety, LADY ALLENDALE led with Cissie Brunton in very fine condition. For three blooms of a yellow Japanese variety, S. E. TULLEY, Esq., scored with remarkably fine blooms of Mrs. R. C. Pulling; second, LADY ALLENDALE. The last-named competitor took the lead for three pink Japanese blooms with Mrs. B. Carpenter; A. F. RIDLEY, Esq., second; J. C. STRAKER, Esq., third. The best three bronze Japanese blooms came from S. E. TULLEY, Esq.; second, LADY ALLENDALE; third, J. C. STRAKER, Esq. LADY ALLENDALE also showed the best three crimson Japanese blooms, exhibiting Mrs. G. Monro; A. F. RIDLEY, Esq., second; J. C. STRAKER, Esq., third. For four vases of single Chrysanthemums, disbudded, T. D. STRAKER-SMITH, Esq. (gr. Mr. J. Winder), Howden Dene, won first prize, his Susan and Bronze Molly being very fine; second, J. C. STRAKER, Esq.; third, LADY ALLENDALE. For two vases of Single-flowered Chrysanthemums, disbudded, J. C. STRAKER, Esq., won first prize; T. D. STRAKER-SMITH, Esq., second; S. E. TULLEY, Esq., third.

Decorative varieties were extensively shown and competition was keen in the various classes.

LADY ALLENDALE had the best collection of six kinds of hardy vegetables, and T. D. STRAKER-SMITH, Esq., obtained the second prize.

In the hardy fruit classes, especially Apples, there was a very good competition.

Obituary.

William Ardnahu Leslie.—We regret to record the death, which occurred suddenly on Tuesday, October 18, of Mr. William Ardnahu Leslie. He died at Corniston, where he had been gardener for forty-nine years. Mr. Leslie was well-known in gardening circles and was a regular contributor to the horticultural press. He was an accomplished photographer, and his articles were rendered the more interesting by his fine illus-

THE LATE W. A. LESLIE.

trations of flowers and plants. He served his apprenticeship as a seedsman with the late Mr. Thomson of Glasgow. Mr. Leslie was an exceptionally capable man in many ways, being an expert electrician and having a practical knowledge of architecture and draughtsmanship. Just before his death he was engaged in the erection of extensive glasshouses for the cultivation of Tomatos, at Symington, to be called The Ardnahu Nursery. This will be conducted by his widow, to whom, and to her two sons and two daughters, our sympathy is extended.

If you send a bunch next year, with wood and leaves attached, we might possibly help you. The withering of the stems is caused by shanking, which dries up the stalks of the bunches and berries of the Grapes. Sometimes only a few berries shank, at other times the whole bunch. Shanking is the result of some strain, such as overcropping, destruction of foliage by red spider, checks and chills, the roots getting into cold subsoil, the borders becoming sour, and excessive dryness at the roots. It is very difficult to trace the cause of shanking, or to apply a remedy, but if the above evils are avoided you will not be troubled.

LIFTING AND REPLANTING VINES.—W. T. It would be quite possible to lift vines twenty-two years old, in inside and outside borders, and transfer them to a new site, but this would entail expense, and either the outside or inside roots would have to be sacrificed. The vines would need shading until the roots had entered into the new soil, and frequent overhead syringings in the morning and afternoon would be necessary until the vines had made fresh growth. Much the cheapest and best course would be to plant young vines in the new house, as these would bear fruit so soon as the old and probably exhausted vines would, and they would continue to improve yearly until they filled the house, four or five years hence. If young, established, planting canes are bought from a nurseryman who specialises in their production, they could be planted in early spring, while home-grown green vines could be planted so late as May with every chance of success.

NAMES OF FRUITS.—B. E. 1, and 3, decayed; 2, Beurré Capiaumont; 4, Gansel's Bergamot. J. L. New Bess Pool.—C. E. 1, Mère de Ménage; 2, Pile's Russet; 3, Winter Greening; 4, not recognised; probably a local variety.—H. A. S. S. Gascoyne's Scarlet.—F. T. Probably Monarch.—Altho. 1, Emperor Alexander; 2, Fearn's Pippin; 3, Cox's Orange Pippin.

NAMES OF PLANTS.—D. G. L. Ceanothus dentatus.—E. S. 1, Veronica salicifolia; 2, V. speciosa var.; 3, V. s. var. purpurea; 4, V. s. var. alba; 5, V. s. coerulea; 6, V. s. var. atropurpurea.—D. C. Your plant is Rhus Toxicodendron, the Poison Ivy, which is occasionally, but erroneously catalogued as Ampelopsis japonica.—D. McK. S. Cotonaster Henryana.—J. B. Cupressus obtusa.—S. D. Senecio Grayii.—A. H. L. Rhamnus catharticus (Buckthorn).—C. B. 1, Stachys lanata; 2, Senecio tanguticus; 3, Saxifraga crassifolia; 4, Lobelia fulgens variety; 5, Solidago canadensis.—A. J. D. 1, Berberis vulgaris var. purpurea; 2, Cotonaster frigida; 3, Euonymus latifolius; 4, Pyracantha coccinea var. Lalandei.—S. P. S. Crataegus orientalis var. sanguinea.—H. C. D. Cupressus Lawsoniana var. juniperina.—Benge. Billbergia nutans; this plant will succeed in a dwelling room.—T. P. The specimens were very scrappy and it was impossible to identify them properly in this condition. 1, Primula Auricula variety; 2, Veronica incana (?); 3, Erigeron species; 4, Cistus species; 5, Iberis species; 6, and 7, Helianthemum species; 8 and 11, too scrappy to identify; 9, Cerastium Biebersteinii; 10, Saxifraga canaliculata; 12, Helleborus foetidus.—C. S. C. 1, Cyclamen europaeum; 2, Salvia farinacea.

NEIGHBOUR'S CLAIM OF LAND.—J. A. The mere fact of leaving eighteen inches of land beyond the ditch would not, of itself, deprive your employer of the ownership of such strip of land, but difficulties might arise hereafter, as the adjoining owner might acquire title by possession. It would be better to adopt the usual course of cutting the ditch to the extremity of the land.

Communications Received.—A. T. H.—W. L. S.—C. H.—W. L.—G. F.—F. G.—J. W. M.—H. B. W.—J. E. G. W.—W. A.—J. C.—H. M.—F. J. H.—J. P.—R. W. R.

GRAPE FOR IDENTIFICATION.—W. H. We fail to recognise the Grape; it is a late variety, very thick-skinned and of moderate flavour.

NEW HORTICULTURAL INVENTIONS.

THESE particulars of New Patents of interest to readers, have been selected from the Official Journal of Patents, and are published by permission of the Controller of H.M. Stationery Office.

LATEST PATENT APPLICATIONS.

Abstract Published.

Garden Roller.—Patent No. 277,904.

A new type of roller which should find favour among gardeners and other users, especially so for use on tennis and like lawns, owing to its heaviness, is the recent patent of Messrs. S. A. Scoffin, H. E. Willmott, G. C. Wood and Scoffin and Willmott, Ltd., of Lansdowne Road, Leytonstone. It comprises two or more cylinders of concrete or similar material provided with outer metal casings which act as protective coverings and also as moulds for moulding the concrete, etc.; the outer edges of the roller are rounded or formed with obtuse angles to prevent damage to the surfaces rolled, etc. The outer sides of the metal casings may be rounded off or bent over, but shaped metal rings may be attached to them or to the concrete, or the concrete may be shaped and made to project beyond the edges of the casings. The concrete may fill the casings wholly or partially. The inner edges may be strengthened by metal casings, inwards, at a right-angle. Bearings for the axle are provided with flanges or projections and embedded in the concrete.

THE LATEST TRADE MARKS.

This list of Trade Marks, of interest to readers, has been selected from the Official Trade Marks Journal, and is published by permission of the Controller of H.M. Stationery Office.

MARKETS.

COVENT GARDEN, Tuesday, November 29th, 1927.

WE cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Tuesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in the day.—EDS.

REMARKS.—In this department requirements were very moderate during the past week, with no special demand for any particular subject, with the exception of Roses, of which the supplies have been somewhat shortened by the colder weather, prices are similar to those quoted last week. Amongst Chrysanthemums, Heston White, Mrs. Wilcox and Winter Cheer are most in demand; good disbudded blooms are fairly plentiful at 5s. to 6s. per dozen; small grades are somewhat shorter in supply. The newest lines in this department are some very fine heads of Poinsettias and a few blooms of Iris tingitana. Asparagus plumosus, A. Sprengeri and Maidenhair Fern from home-growers are now receiving more attention. A good supply of Smilax continues to arrive from the Channel Islands. A few boxes of well-berried Holly are now being received from Cornwall. Christmas Trees are also arriving in fairly large quantities, the larger trees being most plentiful at the present time. The first consignment of Mistletoe is expected this week.

REMARKS.—Some slight improvement is noticeable in the general demand, although conditions are somewhat slow for the time of year. Imported Apples from the North American Continent are selling fairly well, but the stocks on hand are comparatively small. The English Apple market is still overburdened with large quantities of medium and second-sized fruits, which are difficult to dispose of at any price. Best cooking and dessert Apples are selling at slightly better prices. A few English Doyenné du Comice Pears are available, but in competition with Californian samples they do not shine. Hothouse Grapes have been selling quite freely and remain in good demand. There is a firm demand for good Walnuts and Chestnuts, while the few Cob Nuts available are selling at a high price.

The Cucumber trade is good and prices are firmer. Guernsey Beans are selling better, and good Beans will continue to sell well for some time to come. The weekly shipment of Madeira Beans was heavier, but prices were better. New Potatoes from Scilly, Guernsey and the Azores remain in quiet demand. Mushrooms are rather more plentiful, but the prices remain fairly good. The salad trade for the time of year is poor but improvement is expected in this section. Cauliflowers are a quiet section in common with green vegetables. The old Potato trade is firm for the best varieties and grades.

GLASGOW.

An average business was transacted at steady prices in the cut flower market during the past week. Supplies of Chrysanthemums were well maintained and were disposed of as follows:—Ada Brooke, specials, 6s. to 8s. per dozen; White Beauty, 5s. to 7s.; Mary Morris and Absolute, 3s. to 3s. 6d.; Sandown Radiance, 2s. 9d. to 3s. 3d.; Duckham, 2s. 6d. to 3s. for 6's; Phyllis Cooper, 1s. 9d. to 2s.; White and Yellow Thorpe, 1s. 6d. to 1s. 9d.; Ada Brooke, 2s. to 2s. 3d.; Florrie King, 1s. to 1s. 6d.; Almirante, 1s. to 1s. 4d.; Cranford Yellow and Mary Richardson, 10d. to 1s. 3d.; Jean Pattison, 10d. to 1s. 2d.; Pink Chieftain, 1s. 6d. to 2s.; and Dolores, 9d. to 1s. Small bunches of H. W. Thorpe sold at 8d. to 10d., and large at 10d. to 1s. 3d.; Carnations were worth 4s. to 4s. 6d. per dozen; pink Roses, dearer, at 6s. to 8s.; white and red, 2s. to 4s.; Narcissi, 3s. to 4s.; and Lilium longiflorum, 2s. 6d. to 3s. 6d. per bunch.

The fruit market was dull, with Apples steady. York Imperials, 28s. to 32s. per barrel; Spys, No. 1, 44s.; Baldwins, 36s.; Starks, 30s.; Kings and Greenings, 44s.; Ben Davis, 25s.; Delicious, fancy, 16s. to 18s. 6d.; Seagrave, 15s.; Grime's Golden, 16s.; Jonathan, 15s. to 16s. 6d.; and McIntosh Red, 17s. to 17s. 6d. Jaffa Oranges made 17s. and first consignments of Valencia Oranges realised the following prices: 300's, 24s. to 26s.; 240's, 28s. to 30s.; and 420's, 34s. to 37s.; Grape Fruit ranged from 20s. to 22s.; and Mandarins, 1s. 8d. per tray; Winter Nelis Pears, 15s. 6d. half-case; Californian, 26s. to 28s. per case; home Grapes, 3s. 6d. to 3s. 9d. per lb.; Belgian Colmar, 1s. 2d. to 1s. 4d.

In the vegetable market, English Cauliflowers averaged 6s. 6d. per dozen; Lettuce, outdoor, 3s. to 3s. 6d.; indoor, 1s. 9d. to 2s.; Endive, 4s.; French Carrots and Turnips, 1s. 2d. per bunch; Guernsey French Beans, 1s. 6d. to 1s. 8d. per lb.; and Mushrooms, 2s. 6d.

TRADE NOTE.

PATENTS AND TRADE MARKS.—Any of our readers requiring information and advice respecting Patents, Trade Marks or Designs, should apply to Messrs. Rayner and Co., Patent Agents, of 5, Chancery Lane, London, who will give free advice to readers mentioning *The Gardeners' Chronicle*.

GARDENING APPOINTMENTS.

Mr. A. O. Marshall, for the past two years gardener to the LADY ELINOR DENISON, Ossington Hall, Notts., as gardener to G. TATE, Esq., Bere Court, Pangbourne, Berks. (Thanks for 2/6 for R.G.O.F. Box.—EDS.).

Mr. W. Everett, for nearly three years gardener to the Hon. LADY FITZWILLIAM, Barnsdale, Oakham, Rutland, as gardener to Lt.-Col. CLARKE, Blunham Grange, Sandy, Beds. (Thanks for 1/- for R.G.O.F. Box.—EDS.).

Mr. H. McMillan, for the past two years foreman at The Gardens, Castle-Milk, Lockerbie, and Leighton Hall, Walspool, as gardener to R. OLAF HAMBRO, Esq., of Kidbrooke Park, at his Scottish Estate, Glendoe, Fort Augustus, N.B. (Thanks for 5/- for R.G.O.F. Box.—EDS.).

Mr. S. Overall, for the past seven years gardener to G. GEARY, Esq., The Cedars, Barwell, Leicester, as gardener to GORDON STEWART, Esq., Send Manor, Ripley, Surrey. (Thanks for 2/- for R.G.O.F. Box.—EDS.).

Mr. Frederick Leighton, for the past eight years gardener at Red Hall, Shadwell, Leeds, has commenced business on his own account at South View Nurseries, Barmby-Marsh, Howden, E. Yorks.

Mr. E. Griffin, for four years gardener to G. S. BARWICK Esq., Inholmes, Woodland St. Mary, Hungerford, and previously for five years gardener to A. BARCLAY, WALKER, Esq., when at Weybridge, Surrey, as gardener to LADY FITZWILLIAM, Barnsdale, Oakham, Rutland. (Thanks for 2/6 for R.G.O.F. Box.—EDS.).

Mr. A. Handley, for the past three years gardener to VINCENT ROBINSON, Esq., Park House, Newark, Notts, as gardener to LADY ELINOR DENISON, Ossington Hall, Newark, Notts.

SUPPLEMENT PLATE.
Smilacina racemosa.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the past fifty years at Greenwich, 40.4.

ACTUAL TEMPERATURE—
The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, December 7, 10 a.m. Bar. 29.9. Temp. 45°. Weather, Dull.

The Maintenance of Pure and Vigorous Stocks of Varieties of the Potato.

ALTHOUGH written primarily for growers of seed Potatoes, the brochure* which bears the annexed title should be in the hands of all gardeners who grow Potatoes; for it will enable them to realise how arduous is the task discharged, and generally extremely well discharged, by those responsible for the raising and distribution of seed Potatoes. It is to them, indeed, no less than to the skill of the cultivator, that yields of this important crop are generally so high. We say this advisedly, notwithstanding the fact that the average yield throughout England and Wales is rather less than seven tons per acre, which is certainly nothing to boast of! A careful analysis of yields in different parts of the country would, we are sure, reveal the fact that this not particularly high average is made up of two components, one repre-

senting the contribution made by really good growers in districts favourable to this crop. This contribution ranges from fifteen to twenty tons to the acre. The other component represents the yield of crops raised by cultivators who are growing Potatoes in less suitable districts and who make no special effort, either by choice of seed or suitable application of fertilisers, to obtain a large crop. It is to the latter class that this booklet should be particularly valuable, for it will force upon their attention the importance of obtaining fresh "seed" from suitable sources rather than persistence in using their own "saved" seed even when the crops from which the seed is taken are themselves of poor yield. Representatives of these two classes are to be found both among farmers and gardeners. That some of the former should have perforce to be content with a seven-ton or smaller crop may be excusable, but there is no excuse for the gardener who works on any ordinary soil if he gets on an average less than eight tons to the acre. Suitable selection of seed and appropriate manuring will ensure in almost all seasons a crop of that modest size. It is not, however, our purpose here to descant upon this subject, but rather to indicate the more interesting points in the valuable booklet now under notice. The first section deals in an admirably clear and simple manner with the methods of rogueing which have to be practised by growers of seed Potatoes, and is accompanied by a description of those characters of foliage and flower, a close observation of which is essential if rogues are to be recognised and eliminated during the early and later periods of growth of the Potato. At a yet later stage attention has to be directed to time of maturing as indicated by the dying down of the haulm and by the form and colour of the tuber and the sprout. This decline is followed by succinct descriptions of the chief commercial varieties of Potato, together with a list of the rogues which are apt to be found in each of them. It is a curious and interesting fact that rogues are very obstinate fellows, as witness the fact that varieties which have gone almost completely out of cultivation, such, for example, as Magnum Bonum, are constantly turning up as rogues. Following on this section is a diagnosis of the characters of new and uncommon varieties, and then comes a description of the rogues themselves, of which, needless to say, there are many. The information contained in these sections make this little book an indispensable work of reference to Potato growers, at all events to those who adopt the common and generally commendable practice of "growing on," home-saved seed for a second year. In the last section a brief account is given of the means by which the most serious Potato diseases may be recognised, and the steps to be taken to mitigate their ravages. Of these diseases, Late Blight is, of course, the most prominent, and disastrously so in the present year. Spraying or, according to more recent experience, dusting with copper-sulphate-lime (Bordeaux mixture) is, of course, the chief means of combating this disease. But growers in wet districts may help themselves to better crops by planting varieties which are to some extent immune from attack of this disease. Among these relatively resistant varieties are Arran Consul, Evergood, Rhoderick Dhu, President, Lochar, Irish Queen, Kerr's Pink, Champion, Irish Chieftain, Langworthy, Golden Wonder and Arran Victory. Even more serious from the "seed" grower's point of view are those diseases of degeneration, Leaf Roll and Mosaic, which are widely spread and ineradicable, except, perhaps, by constant rogueing. Every gardener, unless he is particularly

lucky, finds at one time or another evidence of the existence of these diseases in the occasional (or frequent) occurrence of plants which, when lifted, bear only a small crop of seed-sized tubers. He has also frequent opportunities of seeing the symptoms of these diseases in the undersized, wizened plants which are apt to occur here and there among their healthy, green, upstanding, normal fellows. There are, unfortunately, many of these diseases of degeneration, and the booklet concludes with a succinct description of their several symptoms. These virus diseases are among the most serious and most obscure of all maladies. The affected plant contains something the nature of which is unknown, but which, when inoculated into another Potato plant, is capable of reproducing the disease. Some varieties are more susceptible than others; but none is immune. Yet some plants are in a half-way condition, they carry the virus, but do not exhibit the symptoms of the disease which it engenders. Green Fly and sucking insects are said to be the chief agents in spreading virus diseases from plant to plant, but what the active agent is and where it comes from are for the future to discover.

Our Supplement Plate.—The illustration reproduced as a Supplement Plate to the present issue represents *Smilacina racemosa* as cultivated so successfully by Mr. W. G. Baker, at the Oxford Botanic Garden. This beautiful and graceful, hardy, May-flowering species is found in shaded or partially-shaded places throughout the greater part of the United States of America. It is a Lilaceous subject, occasionally known as False Spikenard, and also as False Solomon's Seal. The small, whitish flowers are produced freely in loose, six-inch panicles that terminate growths which may be from one foot to three feet tall. *Smilacina racemosa* is figured in *Bot. Mag.*, t. 899, under the name of *Convallaria racemosa*, and the accompanying text states that the species was "cultivated in this country by Mr. John Tradescant, junr., in 1656."

"The Gardeners' Chronicle" Almanac for 1928.—Our Almanac for the ensuing year, giving the dates of the principal flower shows in Great Britain and of the meetings of horticultural and botanical societies, is now being prepared and will be published in an early issue of the New Year. Secretaries of horticultural, botanical and other societies are requested to send the dates of their shows, meetings, etc., so soon as possible, in order that they may be included in the Almanac.

Mr. Clarence Elliott.—We have received a very bright and interesting letter from Mr. Clarence Elliott, together with another instalment of his travel notes. He offers his best wishes to all friends for the Christmas season; he hopes to spend his "Christmas holiday" in Juan Fernandez.

Travelling Horticultural Exhibition at Leipzig.—During the period from the 5th to the 10th June next, the travelling exhibition of the German Agricultural Society will be at Leipzig. The town authorities are co-operating heartily to make the exhibition a success, and a large hall and ample out-of-door space are being prepared for its reception.

Keeping Grapes One-hundred-and-fifty-six Years Ago.—A correspondent writes:—I have recently come across a book, dated 1771, called *The Modern Gardener*, or *Universal Kalendar*, by Mr. Hitt, revised by James Meader, in which I found details of a method of keeping Grapes through the winter and which, I feel sure, will be read with interest by gardeners of the present day. It is as follows:—"The ripeness of Grapes is known by their clearness on the bunch, as well as by their softness and mellow flavour; as soon as the frosts come they must be gathered, and the following preparation made for them: Get two or three wooden

* The Maintenance of Pure and Vigorous Stocks of Varieties of the Potato. *Miscellaneous Publications*, No. 3 (revised edition, 1927). Board of Agriculture for Scotland. To be obtained from the Secretary, Board of Agriculture for Scotland, York Buildings, Queen Street, Edinburgh. Price 1s. net, post free.

boxes of a foot deep and about the same breadth; let the length be according to the quantity of Grapes intended to be preserved in them. Sift very fine a good quantity of wood-ashes that have been well-burnt; let the boxes and the ashes be perfectly dry, but not hot; then spread over the bottom of each box, some of the ashes to cover it, four inches deep. This done, in the middle of a fine, dry day, gather some of the best bunches of Grapes; examine them, and pick off the green berries and any that are eaten by insects or decayed; then lay the bunches side by side upon the bed of ashes in the box, the length of the bunch the cross-way of the box. When the bed is covered with them, sift on more of the ashes, and let them run in between the berries, upon every bunch where there is room; then place another layer of bunches, sift over more ashes, and proceed thus till the box is filled; then set it in a dry place, but out of the reach of heat; in this manner let the several boxes be filled; this is a much preferable method of preserving Grapes than is practised by putting the bunches into paper bags, and hanging them up in a room; for by thus covering them with ashes in boxes they will keep good, and be fit for the table during the whole winter." The punctuation is as given in the book; the work is an eminently readable one and full of sound practice. Names of varieties are scarcely recognisable at the present time, but most of the cultural hints are such as are frequently given to-day.

Harvesting the Briar Rose.—October and November are the great months in the Belgian Ardennes for obtaining Briar Rose plants from the hedges. The task is not an easy one, involving as it does breaking a way, hatchet in hand, through the thorns and tangled growths to the selected plants; it requires strength, adroitness, and a tough skin. The harvester presents a strange appearance, clad in stout corduroy, the head and face protected by a wide-brimmed, felt hat; the Briar-gatherer who is experienced and knows the country well can collect fifty or more Briar stocks per day. These sell at one franc or one franc fifty each, according to quality. Thousands are sent from the Ardennes region every year to nurseries in Brussels and in the Belgian provinces.

R.H.S. and Kindred Societies.—During November, representatives of the National Chrysanthemum, National Dahlia, National Sweet Pea, Rhododendron and Iris Societies met in the Library at the Royal Horticultural Hall, at the invitation of the Council of the Royal Horticultural Society, to consider charges for the letting of the R.H.S. halls for exhibitions of kindred societies. Sir William Lawrence, Bart., presided, and Mr. G. W. Leak also represented the Council. The result of this conference is a happy one, for the Council of the Royal Horticultural Society has agreed to provide free hall services, such as the Society provides for its own shows, on the understanding that the Society concerned shall admit holders of Fellows' tickets free of charge, pay the overtime of the staff during the show and during the preparation and clearing of the show, and also the wages of any additional staff required for the purpose. The halls must be used strictly in accordance with the custom of the R.H.S. towards its own exhibitors. The Society concerned will, as hitherto, receive the gate-money.

Calanthe Hexham Gem var. Phyllis.—Mr. Clive Cookson informs us that the Calanthe exhibited by him at the meeting of the Royal Horticultural Society on November 29, under the name of Calanthe Hexham Gem var. 4.B. has now received the varietal name of Phyllis. This fine new Orchid, which received an Award of Merit, was described in our issue of December 3 (p. 452).

A Norwegian Nursery's Centenary.—We have received from the I. J. Moum Nursery, at Trondjem, Norway, a very nicely got up brochure containing the illustrated history of the nursery which is celebrating its one-hundredth year of existence. A frontispiece shows the proprietor and his wife, and the tail-piece a couple of pretty children, apparently the son and daughter of the house. Mr. Moum is to be congratulated

on the progress the business has made, and upon the condition of prosperity which it evidently enjoys.

Mr. Lewis Smith.—Born in Devonshire, on the Earl of Portsmouth's estate, Mr. Lewis Smith spent his earlier years in "red Devon by the sea," and after school days entered the service of Messrs. W. B. Smale and Son, Torquay, where he gained experience in general nursery work, and particularly in the propagation and cultivation of fruit trees and shrubs. As commercial horticulture did not appeal to him, however, he subsequently served in several private gardens, and presently took charge of the gardens at Clarence Park, Weston-super-Mare, where he laid the foundation of a long series of successes as an exhibitor. His next appointment was at Llanvair House, Ascot, where H. J. G. Rebow, Esq., had a very fine establishment. Later, Mr. Smith became gardener to the late Robert Fellowes, Esq., at Shotesham Park, Norwich, where he remodelled and replanted the gardens and became famous as an exhibitor of Orchids, stove and greenhouse plants, hardy flowers, Grapes, Peaches and Pears. On several occasions he won the premier award at Norwich for an exhibit of hardy flowers,

MR. LEWIS SMITH.

consisting of over one hundred kinds and varieties, and on six occasions won the Royal Horticultural Society's Medal offered for the best exhibit in the show. While at Shotesham Mr. Lewis Smith joined the East Anglian Horticultural Club and became its President at a time when Mr. William Allan, of Gunton, Mr. George Davison, of Westwick, and Mr. William Ocle, of Blickling, were enthusiastic members of the Club. In 1911, Mr. Smith went to Cadland Park, Southampton, to take charge of the gardens for Captain Maldwin Drummond. Cadland is a fine old garden, with magnificent walls that offer fine scope for the cultivation of choice fruits and plants. Since the war, Mr. Smith has been particularly successful as an exhibitor of fruits. He has won the Gordon Lennox Cup on two occasions, the Hogg Silver-gilt Medal and the Medal of the Fruiterers' Company, besides scores of first prizes at London, Birmingham, Southampton and Tunbridge Wells, and he has been almost as successful with Orchids as with fruits, as there is now a very fine collection of these plants at Cadland Park, where Captain Drummond takes a very keen interest in all the departments of his beautiful garden. In the autumn of 1925, Captain Drummond appointed Mr. Smith as agent to the whole of the Cadland estate, a position which he continues to hold. The charge of the gardens devolved upon Mr. Smith, junior, whose father now regards the garden as his hobby and recreation rather than his business.

An American Horticultural Trade Directory.

The well-known American publishing firm, the A. T. de la Mare Co., of New York, has issued a useful *Horticultural Trade Directory* for 1928. It mainly consists of a list of nurseries, grouped primarily under States and secondarily under the towns in each state, given alphabetically. There are also lists of societies, a buyer's guide, and one or two other minor features. The usefulness of the book as a reference directory is slightly marred by the interpolation of displayed advertisements among the classified lists and by irrelevant matter (see p. 204), between two States; also, as it is only bound in card, the price seems rather high at \$3.00.

Promising Young Scientist.

Much gratification is being expressed in Aberdeen University circles and among his own personal friends at the continued progress made by Mr. James W. S. Marr, M.A., B.Sc., Aberdeen, in his work as a scientist. It will be remembered that in 1921, Mr. Marr, then a patrol leader in the Boy Scouts, was picked, along with another Scottish lad, from an enormous number of applications, to join Sir Ernest Shackleton's expedition on the "Quest." The conditions were not favourable to the other lad, and he had regretfully to return home, but Mr. Marr went on and remained with Sir Ernest until that intrepid explorer died at South Georgia, in January, 1922. This untoward event upset all calculations, and the expedition had to be abandoned. Mr. Marr returned home and studied Science and Arts at Aberdeen University, where he duly took the degrees of B.Sc. and M.A. In 1925, now well-equipped, he joined the British Arctic Expedition where his duties were largely hydrographical, but he made a fine collection of rare plants in Spitsbergen and Franz Joseph Land, which he carefully collated and detailed in an article in the *Journal of Botany*. For the past twelve-months, Mr. Marr has been engaged, under the auspices of the Colonial Office, in directing the assorting and cataloguing of the many rare specimens sent from the exploring vessels, "Discovery" and "William Scoresby," for the British Museum. Now he has gone forth upon another tour of research work, the venue this time being the Antarctic regions. His first duty will be the establishment of a laboratory at South Georgia, which will be utilised for arranging and handling the numerous specimens of many kinds that will be gathered by the explorers for experts to examine and give their opinion upon. The two vessels mentioned are, meantime, undergoing a thorough overhaul preparatory to setting out on their new quest, the establishment of the laboratory at South Georgia being part of the plan. Mr. Marr's chief duty on this new expedition will be to carefully chronicle whatever is found to be of scientific interest and practical value, and the task is one which his friends know he will enter into with characteristic zeal and zest, and add more triumphs to his already wonderful career. If all goes well, and no untoward incident occurs, Mr. Marr will most likely be away for three years.

Insectivorous Plants.—The next meeting of the Association of Economic Biologists will be held at 2.30 p.m., on Friday, December 16, at the Imperial College (Botany Department, Prince Consort Road), South Kensington, when Dr. G. H. Rodman will lecture on "Insectivorous Plants and How They Live." Students will be cordially invited. The annual meeting of the Association will be held on Friday January 20, 1928, when the President will deliver his address. On this occasion the members of the Association will dine together.

Rhododendron Association.—The Show Committee of the Rhododendron Association has arranged the schedule for the third Rhododendron Show; this is now in the hands of the printers and will be circulated before the end of the year. A meeting of the Council to elect members formally will be held on December 13. All who join before that date will be known as Founder Members, and although the application forms ask for proposers and seconders, the Council will be pleased to arrange this, as a list of members has not yet been published.

Christmas Trees.—If there were no other evidences, the abundance of Christmas trees in Covent Garden would suffice to indicate the near approach of Christmas. These popular symbols of the festive season are represented by examples twenty-five feet or even more in height, and others of varying stature down to midguts about eighteen inches high. But in addition to the Christmas trees in natural form—from the eastern counties, chiefly, and from certain parts of the continent—there are others that have received the assistance of "art." These are coated with cellulose paint, and may be silver, bronze, purple, blue or vivid green. Moreover, sprays of *Abies* and *Picea* are offered, in boxes, also coloured with similar paint.

New Agricultural College for West of Scotland.—At a meeting of the Governors of the West of Scotland Agricultural College, held in Glasgow, on Monday, the 5th inst., it was agreed to rescind a previous resolution recommending that the activities of the College at Glasgow and the Dairy School at Kilmarnock be continued on land to be acquired on the Pollok estate, Glasgow, and accept a revised offer by Mr. John Hannah, Girvan, of Auchencrurve estate, near Ayr, for the work carried on at the experimental farm and Dairy School at Kilmarnock. Mr. J. H. Turner, who presided, explained the negotiations which had taken place between Sir John Gilman, Mr. Hannah and himself, the result of which was that the removal of the college from Glasgow was no longer a condition, and that the new proposals allowed for a total area of 900 acres of land. Mr. Hannah's gift is estimated to bear a value of about £24,000, and he has also agreed to hand over the whole income derived from the land until such time as it is required for college purposes. The income from this source is estimated at between £1,140 and £1,175. The understanding is that the college would have rather more than 400 acres of arable land, and about 140 acres of pasture, while the mansion house would be adaptable easily to the requirements of the college. Hostel accommodation is to be provided for fifty to sixty students. Recognising the great need for enlarged premises for central classes in Glasgow, it was further resolved, on the motion of the Chairman, to appoint a special committee to secure a site and collect funds for the erection, equipment and endowment of a new college at Glasgow. Dr. Murray stated that a new college worthy of agriculture in the West of Scotland, would cost anything from £50,000 to £100,000, and he hoped the project would be taken up with enthusiasm. A suitable letter of thanks for his magnificent gift is to be sent in name of the Governors to Mr. Hannah.

Association of Parks and Botanic Gardens Superintendents.—Under the auspices of the London and District Branch of the above association, a meeting will take place in the Lecture Room of the R.H.S. Hall, Vincent Square, on Tuesday, December 13, when an address will be given by Mr. W. Dallimore, Curator of the Museums, Royal Botanic Gardens, Kew, on the subject of "Trees for Parks, Gardens and Roads; with Special Reference to Towns." The chair will be taken by Mr. A. J. Ashmore, of Peckham Rye Park, at 7 p.m., precisely. All Parks Superintendents and their foremen who may be in London on this date will receive a hearty welcome.

Southport Flower Show, 1928.—Her Royal Highness the Duchess of York has consented to become a patroness of the Southport Flower Show. The National Sweet Pea Society has accepted the invitation of the Southport Flower Show Committee to hold a Northern Provincial Sweet Pea Show in conjunction with the 1928 Southport Show on August 22, 23 and 24. The total income from the exhibition held this year was £10,474 14s. 7d., and the total expenditure £9,157 6s. 6d., showing a credit balance of £1,317 8s. 1d.

Coal Forests.—This was the subject of a delightful and instructive lecture given by Miss E. Barnett to the members of the Aberdeen Natural History and Antiquarian Society in the Aberdeen University buildings last week-end. In a charming and lucid manner, Miss Barnett,

with the aid of photographs and diagrams, led her hearers through the characteristic formation of modern plant groups, including Ferns, Conifers, Mosses, flowering plants, etc., and then back to the primeval coal forests. This was a most interesting part of the lecture, and must have led some members of her audience to look up again their copies of Solms Laubach's *Fossil Botany* and Seward's *Fossil Plants*. Miss Barnett drew a fine picture of great forests full of giant trees, plants and fungi, and then traced some of the descendants of these to the flora in existence at the present day, but greatly reduced in size. She dwelt on the difficulties botanists and geologists had faced in their work of reconstructing the coal forests of the past, and how very slender were the data

TUESDAY, DECEMBER 13: Royal Horticultural Society's Committees meet; Jersey Gardeners' Society's meeting. WEDNESDAY, DECEMBER 14: Wimbledon Gardeners' Society's meeting; London Gardens Guild lecture. THURSDAY, DECEMBER 15: Ipswich Gardeners' Association's meeting; Linnean Society's meeting. FRIDAY, DECEMBER 16: Association of Economic Biologists meet; Manchester and North of England Orchid Society's meeting. SATURDAY, DECEMBER 17: Lancaster Horticultural Association's lecture.

"Gardeners' Chronicle" Seventy-five Years Ago.—*German Stocks.*—Perhaps in the history of German Stock growing, there are few instances on record of plants keeping in flower for such

FIG. 210.—PROTEA MELLIFERA.

Exhibited by Sir Wm. Lawrence, Bart., Burford, Dorking, at the R.H.S. Meeting of November 29. (see p. 452).

they had to go upon. It might be a leaf or leaves here, a stem impression there, and twigs somewhere else. She informed her hearers that it took from 1829 to 1905 to complete the life history of one of the plant forms. Some of our Ferns and creeping plants were directly descended from the denizens of coal-forests. During her lecture, Miss Barnett showed some fine impressions of fossilised plants and trees in coal seams and peat beds, thus adding greatly to the lucidity of her remarks. A warm manifestation of thanks was Miss Barnett's reward.

Appointments for the Ensuing Week.—MONDAY, DECEMBER 12: National Chrysanthemum Society's Floral and Executive Committees meet; United Horticultural Benefit and Provident Society's meeting; Guildford and District Gardeners' Association's meeting; East Anglian Institute of Agriculture's lecture.

a long period as the following: The seed was sown in the spring of 1850; the plant flowered that season, and towards the end of autumn was potted and placed in a greenhouse, where it bloomed all the winter; in the spring of 1851 it was planted in the open border, still in flower, and continued all summer and autumn. Towards the close of the year it was again potted and placed in the greenhouse, where it kept flowering all the winter. It was again put out in the spring of the present year and had about twenty spikes of flowers on it when planted out; it was early in the season and there were few flowers to bear it company; it bloomed all the summer. When autumn came, however, it showed signs of decay, and the beautiful double blossoms began to get few and far between; but the plant surely did well to keep up a succession of flowers from the summer of 1850 to the autumn of 1852. *P. M. Gard. Chron., December 11, 1852.*

The Week's Work.

THE ORCHID HOUSES.

By J. T. BARKER, Dunstable, Bedfordshire.

Trichopilia.—The genus *Trichopilia* includes about fifteen species; two of them, *T. laxa* and *T. fragrans* were grown under the name of *Pilumna*, but as they succeed under precisely the same conditions they are all included under the same heading, as the geographical area over which the species are dispersed is, comparatively speaking, limited. *T. fragrans* is, as its name implies, a sweetly-scented Orchid, and is one of the very best, fragrant, winter-flowering plants, and should be grown by those who appreciate sweet-smelling flowers. This plant may be grown at the warmer end of the cool house, or in any house where the winter temperature does not fall below 50°. Other species of these interesting plants, such as *T. suavis*, *T. s. alba*, *T. coccinea*, *T. tortilis*, *T. crispa*, *T. marginata*, *T. laxa*, *T. Backhousiana*, and a few others, require a few degrees more heat and a slightly drier atmosphere, as they detest a damp position during their resting season. The majority of these plants will have completed their growth and should be watered with care, or their pseudo-bulbs and leaves will quickly become spotted and disfigured; over-watering at this season also causes many of the roots to decay. So long as the bulbs remain plump, very little or no water will be required, but should they show signs of shrivelling, a moderate amount of moisture may be afforded them. During their resting period the members of this section of *Trichopilia* should be placed in a cool, dry part of the house, where an intermediate-house temperature is maintained. They are fond of a light position, but not actual sunshine, as the leaves soon lose their green appearance when exposed to the sun. When showing their flower spikes the plants may be placed in a shady position in the *Cattleya* house, as they will open better there and be less likely to become spotted by excess of moisture.

Culture.—The different species have individual peculiarities, but the close observer will soon discern their requirements. *Trichopilia*s should be repotted soon after growth commences, and a clean fibrous mixture similar to that used for other small-growing Orchids is suitable for them. Plants now flowering should be potted early in the spring, as it is advisable to defer repotting until the days become longer, and the growing conditions have improved. When in full growth, they will need as much water as any cool-house Orchid, and when well-grown are beautiful and interesting plants. The hybrid *T. Gouldii* (*fragrans* × *suavis*) first flowered in 1911 and succeeds under the same conditions as the other members of the genus.

THE KITCHEN GARDEN.

By R. H. CROCKFORD, Gardener to THE RT. HON. LORD WAVERTREE, Horsley Hall, Gresford, N. Wales.

Mushroom House.—Continue to collect manure and make fresh beds for the purpose of maintaining a supply of Mushrooms throughout the season. When beds are beginning to decline and are becoming dry, holes should be bored at intervals, and warm, weak, liquid manure poured into them. Failing this, mix about half an ounce of salt in each gallon of warm water, and apply in similar fashion. Keep the atmosphere of the house humid by frequently damping the walls and floors, trying, so far as possible, to imitate the conditions of a warm September night. Do not allow the temperature to rise above 55°, or the Mushrooms will be loose and leggy; use as little artificial heat as possible, sweet fermenting materials which give off gentle heat being much preferable. Where woodlice are troublesome, use hollowed pieces of Potato as traps. Bring successional batches of Seakale, Chicory, Dandelion and Rhubarb into the Mushroom house or a separate forcing house.

Early Potatoes.—Now is a good time to commence the forcing of Potatoes to provide a few very early dishes. For this purpose nine-inch or ten-inch pots are suitable. These should be well-crooked and about half-filled with friable soil, consisting of loam and leaf-mould. Insert three or four nicely-sprouted tubers, each with one strong sprout, and cover them with about three inches of the compost. Very little water will be needed for some time to come, and a temperature of about 50° will be suitable to commence with. When growth appears above the soil, place the pots in a light position, as near to the glass as possible so as to keep the foliage sturdy. First Crop, May Queen, and Sharpe's Victor are good varieties for very early forcing.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to COLONEL SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Orchard House.—Where very early Peach and Nectarine trees have been helped forward by the use of mild fermenting material, the buds will now be on the move, but no advance on 45° to 50° through the night should be made before the trees come into flower. So soon as the petals begin to show colour the house should be fumigated mildly on a calm day and well syringed the following morning to ensure immunity from fly during the time the trees are in flower. When the flowering stage is reached, a little more fire-heat will be necessary, particularly through the day, as Peaches always set best when a free circulation of fresh air accompanies the opening of the flowers. A little less moisture at this stage will be beneficial, but unless the weather is wet or foggy the walls and paths may be damped while gentle warmth is turned on for the day. From this time onwards the temperature may range about 60° through the day, and 50° at night, according to the outside conditions.

General House.—The weather has been too mild for flower buds, even in the open air, therefore this softening tendency should prompt all who value their crop to be prepared to house pot fruit trees on the eve of any change. The end of this month or early next month is quite soon enough to close the house; meantime, the pots and trees may be cleansed and finally arranged. The main object in the management of this house—which may contain the latest batch of Peaches, Pears, Apples, Plums and Cherries—is to secure good crops of fruit which shall lead up to and connect with crops from the open air. This end can be attained in a very ordinary glass structure, and often without the aid of fire-heat; the most important point at this stage is complete rest for the trees, not only before but for some time after they are housed. As the natural flowering season comes round the buds on the trees are sure to be in advance of their fellows in the open, and when this stage is reached retarding ends, and a temperature suitable to the opening of the flowers and the setting of the fruits must be maintained. If the pots are plunged in litter the roots will take no harm, but a sharp look out must be kept to prevent damage to the buds by birds.

Potting.—If pyramids and other forms of home-grown trees have not yet been lifted for potting no time should be lost in getting the work done. When late trees are potted in December the roots should be carefully pruned as a preliminary to ramming rather dry soil about them. Gardeners who make a first essay at orchard house culture should invest pretty freely in trees of choice Pears, as these will give a good return for the labour expended on them.

Cucumbers.—Plants in full bearing need frequent applications of warm, liquid manure and judicious syringing with tepid water, but unless plants intended to supply fruit from January to March are decidedly weak, the rough compost, kept properly moistened with clear water, should maintain a medium and healthy growth which will not suffer when bad weather arrives. Old fruiting plants intended for

removal so soon as young ones are bearing, need a temperature of 66° to 70° by night, and proportionately warmer through the day; they should be top-dressed frequently with rich, rough compost kept handy in a warm corner for the purpose. The temperature for spring plants may be kept at 63° to 65° at night, with a day circulation of fresh air which should be made warm by passage over the hot-water-pipes before it reaches the foliage.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to SIR CHARLES NALL-CAIN, Broomfield Hall, Hertfordshire.

Stocks.—These are useful subjects for flowering in the early spring, but to be successful with them, and to secure good spikes of bloom, they must not be starved. Plants that have been raised from seeds sown at intervals, as advised, should, as they become ready, be transferred to the receptacles in which they are to flower, and grown on greenhouse shelves near the roof-glass. Failing this accommodation they may be grown in frames from which frost is excluded and where they may obtain the maximum amount of light.

Cinerarias.—Early-raised plants have filled their receptacles with roots and are showing flower. They should be encouraged by discreet waterings with soot-water and the occasional use of some reliable fertiliser. Watch carefully for green-fly, and on its first appearance take steps to eradicate this pest. The better plan is to spray the plants frequently with an insecticide as a preventive measure.

Bulbs.—Care should be taken not to allow bulbs to remain plunged in ashes or other materials after they have started into growth. Remove them to frost-proof frames and gradually expose them to light and air.

Euphorbia jacquiniæflora.—This delightful stove subject is one of the most beautiful and useful plants to cultivate, both as regards its decorative value and the length of time it remains in flower. The flowering sprays may be used in a cut state for filling large vases; long stems are produced when the plants are grown under good conditions. When used in a cut state, however, the stems, should be dipped into nearly boiling water immediately they are severed to prevent excessive bleeding and consequent flagging. Certain growers use a hot iron to seal up the ends, but after trying both methods, I much prefer the former. Continue to afford light stimulants until half the flowers are open, after which no feeding is necessary, and when this stage is reached a somewhat cooler temperature is desirable, to prolong the flowering period, but at the same time the atmosphere must be kept slightly drier to prevent the damping off of the flowers. This *Euphorbia* should never be allowed to dry out or loss of foliage may follow; on the contrary, an excessive use of water at the roots and sudden fluctuations of temperature will produce similarly unpleasant results.

HARDY FRUIT GARDEN.

By H. MARKHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet, Middlesex.

Grafting.—Notes should be made of all unfruitful and inferior varieties of tree fruits, and if the stocks are healthy, grafting with more suitable kinds should be carried out when the proper time arrives. In the meantime, scions of desirable varieties should be collected, tied up, labelled correctly and heeled in on a north border until they are needed. When shortening back the branches to obtain grafts do not cut too severely, but shorten the branches more or less according to the shape and thickness of the stems on which the scions are to be placed. Trees grafted last season should receive attention, reducing the number of growths to those required to form well-shaped heads. Prune side-shoots back to within a few buds of their bases and allow each leader to extend more or less according to its strength and length. All temporary supports should be replaced,

SMILACINA RACEMOSA.

as necessary, until the grafts are sufficiently strong to withstand strong gales when in full leaf. Keep the stems and trunks free from young growths so that the young scions may receive all the support possible from the old stock.

Strawberries.—The growth of Strawberries is much better this season than during the past three or four years, and if the plants pass through the winter without being crippled by severe frost and cutting winds there should be a good crop next year. If not already given, a good mulching of manure should be placed over the roots and along the space between the rows; this will greatly benefit the plants in spring and also protect the roots against very severe frosts.

Reminders. — Examine Gooseberries and Currants at frequent intervals, especially where sparrows and other birds are numerous and destructive to the buds, as an oversight in this respect may result in a serious loss. Frequent dustings with soot, lime, and wood-ash may ward off attacks, while lines of black cotton strung along at various heights above the bushes will also serve.

Fruit Trees.—Where hares and rabbits abound, newly-planted fruit trees should have their stems painted with Bentley's tree-protecting dressing, or protected with strips of wire-netting, otherwise much harm may be done in a single night.

THE FLOWER GARDEN.

By JOHN COUTTS, Assistant Curator, Royal Botanic Gardens, Kew.

Arbutus.—The genus *Arbutus* comprises evergreen shrubs or small trees of much beauty, but these are not hardy all over the country, especially in inland districts. They are, however, quite hardy in the south and south-western counties, and all up the west coast of Scotland—a sufficiently wide range to justify their more general cultivation. They prefer a well-drained, warm soil and a sheltered position, otherwise their successful cultivation presents no difficulty. Although they make handsome specimens individually, they look best when planted in a small grove. At Kew the species mentioned below are perfectly hardy and generally attain a height of fifteen to twenty feet. *Arbutus Unedo*, the Strawberry Tree, is the most common species, and is a native of south Europe and the west of Ireland. It is at its best from October to December, when it is in flower and bearing the previous year's fruits, which are then a bright red. There are several varieties, the best-known being *Croomei* or *rubra-compacta* and *integerrima*. *A. hybrida* (*Andrachne* × *Unedo*) makes a handsome group and always attracts attention by its smooth red and green stems, the bark being shed annually. *A. Andrachne* is a native of Greece, and although introduced in 1724, is by no means so common as it should be—nursery stock being scarce—as it is a handsome evergreen, and a grouping of it, with its smooth, polished stems, is very effective. Another beautiful species is *A. Menziesii*, from north-west America; this somewhat resembles the last-named species in leaf, and in its even more highly-coloured stems; it is the Madonna of California. *Arbutus*es are propagated by means of seeds and grafting.

Ixias.—The many beautiful varieties of *Ixias* are generally regarded as greenhouse plants, but in favoured parts of the country they succeed in beds in the open, in sheltered positions. They should be planted in light, warm soil, in beds raised slightly above the surrounding level. They do well when planted in narrow borders at the foot of a warm wall, and should be more generally grown in such positions. In these situations they increase and flower year after year. They may be planted during December and January; if planted earlier they quickly come through the ground and make considerable growth which runs a risk of being injured during severe weather, although in this respect they are hardier than is generally supposed. *Babianas* and *Sparaxis* also succeed and should be planted under similar conditions.

FOR NORTHERN GARDENERS.

By A. T. HARRISON, Gardener to the MARQUIS OF AILSA, Culzean Castle, Maybole, Ayrshire.

Root Cuttings.—The present time is most suitable for inserting root-cuttings of various plants which are not readily increased by the usual methods, and where it is desirable to increase such subjects as *Anchusas*, an old plant should be lifted carefully and the long thong-like roots removed, replanting the dismembered plant in good sandy soil, where it may be expected to recover and grow again. The thong-like roots should then be cut up into two-inch or three-inch lengths and placed on their sides in boxes of sandy compost,

Miniature Hyacinths are grown in boxes it is a curious fact that a few of them will always push on ahead of the rest, and if these are lifted carefully and made up into pans with a few Ferns from small pots, they will prove useful for the earliest decorations.

Lily-of-the-Valley.—This is a general favourite, and by means of retarded crowns may be had in flower almost at any time, but as the plants treated in this manner are short-lived, if not killed outright by the retarding and forcing treatment, it seems almost cruel to treat them in this way. Where established beds of Lily-of-the-Valley are grown, a portion of the batch may be lifted each year and the flowering crowns selected for forcing, while the smaller

FIG. 211.—CHRYSANthemum MRS. E. PAGE.

N.C.S. First Class Certificate, Nov. 23; R.H.S. Award of Merit, Nov. 29. Flowers golden-yellow, shading to bright chestnut (see pp. 475 and 452). Shown by Mr. H. Woolman.

covering them about an inch deep, more or less, according to the thickness of the roots dealt with, and placing the boxes in a temperature of about 50°. In a very short time new growths will be produced. Quite a variety of plants may be rapidly increased in this manner, and where all other methods have failed, it should be given a trial. *Tropaeolum speciosum* is an instance, while *Romneya Coulteri* and any specially good forms of Oriental Poppies may be increased rapidly by this method.

Bulbs.—Where these are required in flower for Christmas, much care is necessary in forcing, and any that show a tendency to outstrip the others should be removed to the cooler end of the forcing house, or placed in a lower temperature, where they will "mark time" until the others have caught up. Where Roman and

crowns may be replanted in beds of well-prepared soil, where, in the course of a year or two, they will also be ready for lifting. These home-grown crowns require a longer time than retarded crowns to bring them into flower, and nothing but disaster will result from the use of excessive heat in the early stages of growth; they should be brought on gradually and the temperature raised as growth becomes active. When flowering is over, these plants, if treated rationally, may be replanted; given generous treatment, they will soon recover, and in course of time again produce crowns fit for forcing. Beds of Lily-of-the-Valley have been a wonderful sight again this autumn by reason of the numerous spikes of red berries amongst the brown foliage; many visitors have had to examine the plants closely to ascertain what this lowly form of berried plant really was.

BUTTONHOLE ROSES.

ENGLISHMEN are not particularly partial to the "buttonhole" bouquet. The reason, one supposes, is the dislike of being conspicuous and different from one's fellow men. Perhaps, too, there is a feeling that the wearing of a flower borders on the effeminate. Buttonholes, I fancy, were more in vogue in Victorian times—strange though it may sound in an age somewhat sombre and austere. The buttonhole generally approved, or shall I say, condoned, is the one taken from one's own garden—the unstudied buttonhole. Men rarely enter a shop with the express purpose of buying a flower for the coat, unless it be for a special occasion, such as a wedding. The wearing of buttonholes by city men is to be encouraged. It brings brightness into drab surroundings.

Of flowers suitable, probably the Carnation takes the lead on account of its lasting property; but none appeals like the Rose. Unfortunately, unless supplied with water, it soon shows signs of distress and before the day is over has lost its freshness. The careful business man, while in the office, transfers it to a vessel of water; but a better way is to supply its wants while actually in the coat by means of a flower-holder. The metal kind, with movable clip, now in use, is ingenious and handy. It has two drawbacks. The bright bit of metal which hooks the holder to the buttonhole is exposed to view. It might be rendered inconspicuous by green enamel. The clip weakens in time; thus failing to hold the flower firmly. A more satisfactory kind of holder, though entailing more trouble, consists of a flattened glass or metal tube made to fit into a little pocket of thin material sewn on the back of the lapel of the coat. This method permits the use of a pin inside, just below the buttonhole, thus affording greater security. Such tubes used to be obtainable. Are they still in use?

A coat flower, as a rule, is incomplete without some foliage. Needless to say, the Rose's own leaf is its best accompaniment. Without water it wilts more quickly than the Rose itself. A flagging leaf spoils the effect of a buttonhole, even though the actual flower may appear fresh. Failing a water-holder, a good substitute for the Rose's own foliage is the leaf of the evergreen Barberry (*Mahonia*). It is similar in form, and in these days of stiff-leaved Rose varieties it is hardly distinguishable at a little distance from that of a Rose. This Barberry leaf keeps perfectly fresh the whole day without water, provided a mature one is used.

It is not the fully open Rose, but the partially expanded bud which is favoured for the buttonhole. All Rose buds are by no means suitable. A variety which gives a full bloom when expanded—the exhibition sort—is rarely so. The bud is too fat and solid looking, and usually ceases to open further in water when cut. The ideal bud is one which is not exactly static in the buttonhole, but unfolds to some degree as the day advances. The varieties which furnish the best buttonholes belong to the semi-double or even single class.

Taking the older group, the Hybrid Perpetuals, now a fast waning set, make unsatisfactory buttonholes, as they are mostly very full Roses, and also they lack, as a rule, the high, pointed centre, so desirable a feature. Perhaps the crimson Captain Hayward, being a rather thin Rose, is as suitable as any, likewise the very fragrant Fisher Holmes, of similar colouring; while Frau K. Druschki, if not of exhibition size, suits a dark coat.

Before the advent of the Hybrid Teas we had chiefly to rely on the pure Teas for buttonholes, and were often therefore dependent on the greenhouse. Now it is far otherwise. We can rely upon a supply from our Rose beds in the open from June to October, and even, in mild seasons, up to Christmas. The Rose buds most favoured are those of yellow, copper or salmon shades. Let us, however, deal with the reds and pinks first.

The most popular bedding red Rose, General McArthur, often makes quite a passable buttonhole, and if scent is required it is here in abundance. Richmond, however, is much nearer the ideal, but it lacks the vigour and certainty

of the General. Liberty, darker and more velvety, has a too feeble constitution for the garden, though it is still grown under glass for the cut-flower trade. Hoosier Beauty, also a market Rose, gives a fine, dark-crimson bud, but its lax habit makes it a somewhat unsatisfactory bedder. The scentless Red Letter Day and K. of K., though of few petals, rarely give a bud of sufficient distinction. The velvety-crimson Colonel Oswald Fitzgerald and Miss C. E. Van Rossem are generally suitable, but scent here is also lacking. H. E. Richardson can, at times, give a shapely, deep crimson bud, full of perfume, but it is a variety that produces more shoots than flowers. Covent Garden is to be recommended, if scent is not required. Red varieties suitable both for the garden and the coat are not numerous.

The pink sorts show up better. We have almost the ideal in Dorothy Page Roberts; a grand grower, though on the tall side, fragrant and a free-flowerer. It withstands rain remarkably well. A Rose to be mentioned here, though hardly a pink, described as a copper-salmon, shaded fawn, is Mrs. Alfred Tate. It gives a similarly shaped bud, but it is, unfortunately, easily spoilt by rain. That long-tried and excellent Rose, apart from its habit, Madame Abel Chatenay, is a little too full to give an ideal bud. Ophelia and its more deeply-coloured sport, Madame Butterfly, furnish exquisite buds, but as they meet our gaze in every florist's window we may want something a little different. Ivy May, of recent origin, just as shapely and finely scented, is a change. Betty Uprichard, rich in colouring and now at the height of its popularity, does not appeal strongly to me as a buttonhole Rose. But Mrs. Henry Morse does; when not too full and large. It is perfect in shape. Alas! it is rather addicted to mildew.

Passing to the more coppery pinks, there is a buttonhole Rose *par excellence* in Betty. This variety has almost the largest bud of any. Once largely grown, it is falling out of favour. It may be owing to the floppy character of the flower after the bud stage, or to its undecided colouring. It is a vigorous grower, rainproof, and fully fragrant. It certainly deserves a high place as a buttonhole Rose. Of the orange-crimsons, Henrietta is to be preferred to the more startling Madame Edouard Herriot. It has a stiffer stalk, some fragrance, and is less easily affected by rain.

Of the full coppers or oranges we have a gem in Emma Wright; but what a name for such a dusky beauty! It produces a most telling bud for the buttonhole, provided the flowering is not too profuse, when it may be on the small size. To pick faults in this variety would be approaching the hypercritical. Independence Day, of a more yellow shade, also gives a delightful bud. This is a Rose of much excellence, but is not as vigorous as the preceding one. A new Rose of continental origin, Wilhelm Kordes, promises well as a buttonhole Rose, from what I have seen of it.

The stricter yellows may be conveniently divided into those of Tea (*Rosa indica odorata*) origin, and those which derive this colour from the Austrian briar (*R. lutea*)—the so-called Pernetiana group. Of the former, Lady Hillingdon, Gustave Regis, Madame Ravary and Mrs. Aaron Ward may be mentioned as among the best for the buttonhole. The first is a pure Tea and fairly hardy. It gives a long bud, of rich colouring, but on account of its pliable habit of growth it does not make a good bedder. Gustave Regis is a "weeny." It appears to be falling out of cultivation, perhaps owing to its being neither a climber nor a bedder. Such Roses are rather difficult to place and to manage. It is an ideal buttonhole Rose of a light shade of yellow. Madame Ravary used to be the popular yellow bedding Rose, but it has had to give way to the Pernetiana yellows. It is sweetly perfumed and can have captivating colouring, but as an autumnal it is of little value as its blooms usually come thin and a dirty, washed-out white. It somewhat lacks "point" in the bud, that is to say, it is a little too squat. As a buttonhole Rose at times I find it unsatisfactory through the stalk snapping just below the hip. Mrs. Aaron Ward at its best makes the better

buttonhole, but is otherwise a less desirable Rose. It is apt to come pinkish if the weather be at all cool, and its buds ball and rot badly in the wet.

Though the yellow Pernetianas have been with us for some time, they do not as yet supply ideal buttonholes. To date, there has been little real advance on the well-known trio, Mrs. Wemyss Quin, Golden Emblem and Christine. All three may be used for the coat. Mrs. Quin is slow in coming into bloom, and is rather pale in colour, but it has most fragrance. Golden Emblem is stumpy in growth and consequently blooms sparsely. Christine, on the other hand, flowers profusely, but in clusters, so that the individual bloom is apt to be on the small side for the coat. Of the newer yellow Pernetianas, Mabel Morse is too large and globular for a buttonhole Rose, though useful otherwise. Sovereign, though shapely, is a wretched grower. Florence Izzard may be suitable, but I have had no experience of it.

Of pale Roses—whites and creams—the pure Tea, Mrs. Herbert Stevens, is distinctly one of the best for furnishing buttonhole flowers. It is hardy, vigorous and a free-flowerer, bearing a perfectly shaped bud. Its spindly growth reduces its value as a bedding Rose, and its bloom does not stand wetting very well. Clarice Goodacre, pale chrome, has a finely formed bud and a good bedding habit. Madame Pernet Ducher, a hardy Tea variety, creamy-yellow in the bud and white when full blown, has apparently fallen out of the catalogues. I still find it worth growing for the sake of its pleasing buds which carry the full Tea scent.

Of the true single Roses—those of five petals only—Irish Fireflame deserves mention as it makes an excellent buttonhole. It surpasses Irish Elegance, its forerunner, in its more vivid colouring and greater length of bud. Isobel, of more recent origin, does not make the same appeal to me as the two foregoing. *J. P., Carlisle.*

BULB GARDEN.

LILIUMS.

WHERE stocks of Liliams need to be replanted, the work should be done so soon as possible, as many of the kinds commence to grow early. The same observation applies to purchased bulbs, and if for any reason these cannot be planted at once, they should be unpacked and laid out in boxes, covering them with leaf-soil, as they quickly suffer if exposed to the air. Species that produce stem roots appear to withstand removal better than those that have basal roots only; I mean that stem rooting species usually give a good display the first season after planting, whereas, in my experience, most of the species that do not produce stem roots require one season to recover. Of course, they vary even in this respect, but if we consider species like *L. chalcedonicum* and *L. monadelphum*, no matter how quickly and carefully they may be transplanted they invariably require a whole season to recover themselves; therefore, when they are growing well they should be left undisturbed so long as possible.

The first essential in the successful cultivation of Liliams is free and rapid drainage, for stagnant moisture during the winter quickly proves fatal. Although some Lilies grow freely in any fairly light, well-drained loam, it is always wise to put plenty of clean, coarse sand around the bulb at planting time. Liliams generally do well when planted among beds of dwarf shrubs, from which they receive shelter from cold winds and frost during spring; during the summer the shade from the shrubs helps to keep them cool at the roots. All stem-rooting Liliams should be planted deeper than the non-stem-rooting species. As a general rule, six to eight inches (according to the size of the bulb) is deep enough for planting the stem-rooting species. Many of these delight in plenty of humus, such as well-decayed leaves; avoid peat unless it is permeated by roots of Rhododendrons or other shrubs. *J. C.*

HARDY FLOWER BORDER.

HELICHRYSUM BRACTEATUM.

THIS charming and comparatively new introduction from Tasmania is well worthy of a prominent position on a large rock garden, or in the front of a flower border. It is quite distinct from the strain of garden Everlasting Flowers usually grown under this name. Perfectly hardy and perennial, it produces in late summer and autumn masses of sharply-pointed, egg-shaped buds on foot-high stems in an attractive shade of bronze, which expand into beautiful old-gold, everlasting flowers. The plants shown in the accompanying illustration (Fig. 212) are growing in a west-facing border, fully exposed, and stood out in the open all last winter. It is difficult to imagine a prettier sight than that presented by this sheet of golden-yellow, and the flowers seem to open day after day interminably. *Helichrysum bracteatum* is increased readily from seeds, comes perfectly true, and seems best suited when grown in full sun and a deep, fibrous loam.

The number of good hardy perennial plants which Tasmania is giving us nowadays for our gardens is rather surprising. Another dainty Everlasting, recently introduced, is *Helipterum anthemioides*, which does excellently under the conditions suitable for *Helichrysum bracteatum*. Its slender, nine-inch growths somewhat resemble those of a *Linum*, and in late summer are surmounted by charming, white, papery Daisies. It looks lovely in the evening, when the light commences to fade and the fragile stems seem to disappear, so that the flowers appear to be poised, fairy-like, in the air. This also is easily raised from seeds. *Will Inghersen, The Birch, Sharpthorn, Sussex.*

HERBACEOUS PAEONIES.

THE herbaceous Paeony, one of our oldest and most loved hardy perennials, has found a place in almost every garden of the country, and is firmly established in the affections of all garden lovers, whether they be owners of the tiny cottage gardens or of more extensive domains. It is not, therefore, necessary to extol its popularity, but the modern development of the plant has led to an even greater admiration of it and opened up a wider field for its uses.

Amongst the many points which make it a valuable garden plant may be mentioned its perfect hardiness and power of resistance to inclement weather, its sturdy habit, wide range of colours in the most exquisite tints which would have been thought impossible a few decades ago, its suitability for house decoration, its delightful fragrance, and its adaptability to a great variety of soils and positions.

All that can possibly be said against the Paeony is that it takes time to become thoroughly established, and that its season of flowering is relatively short, but even on these points there are compensations, for once established it is truly perennial and gives little further trouble for a number of years, and after the season of flowering is over, its massive foliage is not lacking in beauty and takes on brilliant tints of orange, scarlet and crimson in the autumn.

As already noted, the Paeony is adapted to a variety of positions, and is equally attractive as a specimen in the herbaceous border, in beds on the lawn, as single specimens in the front of the shrubbery or in bold groups in the woodland garden. In these days of special gardens, too, a section might be devoted to Paeonies and, with the large amount of material available, the Paeony garden might be made a highly attractive and interesting feature. Such a garden could be enclosed with a Yew hedge, and would present a magnificent spectacle in June and July, and if late summer or autumn colour is desired, *Liliums*, such as *L. auratum*, *L. speciosum*, *L. Henryi* and *L. pardalinum* could be planted between the Paeonies. The foliage of the Paeonies, with the Lily flowers overhead,

would make a pleasing combination, and neither need be disturbed for a number of years.

Reference has been made to the adaptability of the Paeony to a great variety of soils, but as the plants usually occupy their quarters for a long period without disturbance, it is essential that thorough preparation should be made for them. A good, medium, deeply-worked loam suits them best, and on soils of a light nature heavy dressings of organic manure should be incorporated with it before planting. The massive foliage denotes that they are rank feeders, and established plants should be fed regularly to maintain their vigour. A top-dressing of rotten manure forked into the surface soil early in the year is very beneficial or, failing that, a dressing of bone-meal may be given.

The number of beautiful varieties is so great that it would need a long list to include all the best, but there are sufficient to meet every possible taste in both the single and double sections, the colours ranging from the purest white through every shade of cream-pink, and rose to the deepest crimson. *W. Auton.*

FIG. 212.—HELICHRYSUM BRACTEATUM.

ALPINE GARDEN.

ANDROSACE CARNEA.

AT one time regarded as difficult plants to cultivate in our gardens, it is now recognised that quite a number of the Androsaces, or Rock Jasmines present as little difficulty as the majority of other alpine flowers. Some, it is true, require protection from wet in winter in localities with a heavy winter rainfall, but in dry parts of the country where properly planted this is not necessary. *Androsace carnea*, however, does not require even this, and it has been cultivated successfully even in wet localities without anything to throw off the rain.

It is a most attractive little Rock Jasmine, which will flourish either in the crevices between the rocks or on a level or slightly sloping part of the rock work, where it is planted in light, peaty soil with plenty of grit and the freest drainage. There it should spread into little lovely low cushions or mats composed of small, bright green foliage with hardly any hairs except on the edge. On this are set the lovely pale pink flowers, elevated on stems two or three inches high, and presenting, in association with the emerald of the leaves, a combination of perfect charm.

The precise shade of pink varies in different plants, some of which have been dignified with specific or varietal names, although this seems rather superfluous where the plants naturally vary greatly. One of the finest of

these is that called *A. carnea* Lageri, or, very frequently, simply *A. Lageri*. This is dwarfer and neater in its deeper shade of green foliage, and is made more precious by the increased brilliancy of its pink flowers, which are in addition, more lavishly borne on the plant. *A. carnea* eximia is also a charming and brighter-coloured variety now quite scarce in gardens.

MODIOLA GERANIOIDES.

IT is a little puzzling to ascertain the exact title of the little plant which I have known under two or three names, but which I have lost sight of for some years, although it is still in commerce. Forty or more years ago, I purchased it under the above name, but afterwards saw that it was said to be synonymous with *Malvastrum Gilliesii*. Then the *Kew Handlist* recorded it as *Modiolastrum geranioides*, a title which I could not find in the original volumes of the *Index Kewensis*. A reference to the various entries in the latter work does not help one much, as *Malvastrum geranioides* and *M. Gilliesii* are both given under the heading of

Malvastrum. Mr. Reginald Farrer retained the name of *Modiola geranioides*, which I am also employing, in writing of this plant. This information may be said to be purely academic, but it is important that intending purchasers of a plant should know by what titles it may be found in lists, and it is exceedingly annoying to find such differences in the nomenclature of such a pleasing little plant.

Modiola geranioides came to me originally from Messrs. Barr and Sons, and was appreciated by the writer and his friends who were interested in rock garden plants. It gave much pleasure with its trailing habit, its pretty, divided leaves and its numerous, carmine-cherry-coloured flowers of medium size. It proved an excellent plant for the rock garden, and had only one failing, though this was a serious and disconcerting one. It did not appear able to resist a severe winter in our climate. After a year or two it died, and many replacements which I made afterwards in this and other gardens met with the same fate under similar conditions during the winter months.

It is not difficult to understand why this *Modiola*, or *Modiolastrum*, should be tender, as it transpires that it is a native of Chili, though Mr. Farrer said that it was a native of North America. Yet I feel pretty confident that there are many rock gardens in the milder parts of the British Isles where, at least in warm, sheltered positions, it can be grown with success and will prove hardy. It loves a light, well-drained soil, and not only for its scarcity, but also for its beauty, it merits the consideration of those who are about to plant alpine flowers. *S. Arnott.*

INDOOR PLANTS.

ANCHUSAS IN POTS.

THE varieties of *Anchusa italica* are very useful for cutting or grouping when grown in pots. One-year-old plants are the most satisfactory, and they should be potted now in eight-inch or ten-inch pots, according to the condition of the roots. A compost of rich loam and sufficient gritty material to make it porous suits them well. The plants should be grown under cool conditions in a greenhouse where frost is excluded. Liberal feeding may commence when the flower spike has formed. *S. Bowler, Ford Manor Gardens, Lingfield.*

CYRTANTHUS MACKENII.

I MAKE no hesitation in stating that *Cyrtanthus Mackenii* is a plant which deserves to be more widely grown. In fact, there is no reason why it should not become as popular as the *Freesia*, which requires identical cultural requirements. Plants which provide us with flowers at Christmas—as this does—are always welcome, especially if they are suitable for cutting for room decoration.

C. Mackenii is a bulbous, Amaryllidaceous plant, which has long, white, tubular, sweetly-scented flowers. They are about two inches in length, half-an-inch across the top, and taper off to a very narrow tube at the apex of the ovary. The perianth tube is curiously twisted, from which characteristic the plant derives its generic name, *kyrtos*, meaning to curve, and *anthos*, a flower.

As a general rule there are about half-a-dozen flowers in an umbel on a long, stout flower-stalk that carries them well above the narrow, grass-like, arching foliage.

I first became acquainted with the possibilities of this *Cyrtanthus* when visiting the garden of a friend who made a speciality of its culture. At that time he had a large batch of plants in five-inch pots, and as these were in full bloom they made a remarkable and impressive sight. My friend informed me they were not difficult to cultivate, and that very little fire-heat was required to induce them to flower during the winter.

Increase is rapid, as offsets are freely produced, so that a large number of plants may be quickly obtained. The bulbs—which are similar in size and shape to those of the *Jonquil*—should be potted up in September, using a compost consisting of two parts of turfy loam, one part of leaf-mould, and sufficient silver sand to ensure porosity. Six bulbs are sufficient for a five-inch pot, and they should be planted so that their tops are just above the surface of the soil.

After potting, stand them in a cold frame until well rooted, when they should be placed in a slightly heated greenhouse. As *Cyrtanthus Mackenii* is a native of South Africa, it is best to grow it under cool conditions, otherwise the flower-stalks will become weak and unable to properly support the inflorescence.

After flowering, it is necessary to feed the plants occasionally with a complete fertiliser, until March, after which they should be gradually dried off previous to resting them entirely during the summer.

C. Mackenii was introduced to this country in 1774, and is figured in *Bot. Mag.*, t. 335. *G. F. G.*

GLADIOLUS COLVILLEI
THE BRIDE.

WHERE quantities of choice flowers are in demand during the spring and early summer months, *Gladiolus Colvillei* The Bride is indispensable. The pure white flowers, produced in long, slender sprays, are admirable for all kinds of decorations, and when grown in five-inch pots the plants are exceedingly useful for the embellishment of the greenhouse and conservatory.

The corms may be obtained during October when an early batch should be potted. Almost

any rich soil will suit them; good loam, with the addition of one-sixth of old Mushroom-bed manure and some good coarse sand is an excellent compost.

After potting, plunge the pots in a bed of leaves or Coconut fibre refuse in a cold frame. If the soil is in a moist condition at potting time no water will be required until growth appears above the soil. The pots should then be removed to a light position near the glass in a house with a temperature of 50° to 55°, and when the growths are two inches high they may be subjected to a slightly higher temperature.

Abundance of water is necessary at all times; and weak stimulants may be applied so soon as the flower spikes appear. The foliage will require the support provided by a few small sticks or twigs.

FIG. 213.—LARGE SITKA SPRUCE, DEAD, BUT WITH POLYPODIUM SCOULERI ALIVE ON IT; JANSEN'S ISLAND, BRITISH COLUMBIA.

After flowering, the plants should be gradually hardened off and plunged outside, and supplied with water and stimulants until they ripen naturally. Corms treated thus will be in grand condition for potting in the following September to produce an extra early batch for the next year. Corms from which flowers have been cut are of no further use.

This *Gladiolus* is perfectly hardy and increases freely in the open ground, where a constant succession of blooms may be kept up from March until the end of August.

STRIKING ZONAL PELARGONIUM
CUTTINGS.

THE majority of gardeners strike cuttings of Zonal Pelargoniums under conditions entirely different to those in which most soft-wooded subjects are rooted, and to me it has been a frequent cause of wonder why this should be so. After the cuttings are made it is quite usual to insert them near the sides of pots, or in boxes,

water them in, and then place the receptacles in a frame where little or no protection from sun is afforded. The soil is kept barely moist, water being given only when absolutely necessary until such time as roots are emitted.

Some gardeners carry this method to even greater lengths and after the cuttings are made they will leave them lying about for twenty-four or even forty-eight hours "to dry off," before insertion, and then, if it is early enough in the season, will stand the pots of cuttings out in a sunny position in the open. The explanation usually offered in defence of this procedure is that "*Geranium*" cuttings are of a sappy nature, and by this means some of the superfluous sap is dried out and consequently the cuttings are not so liable to damp off. The same idea prevails in regard to withholding water from the cuttings when they are inserted, and, indeed, this is very necessary if a successful "strike" is to be obtained from material propagated in this way.

Personally, I have always failed to see the advantage of "drying off" the cuttings before insertion, for it seems that immediately they are placed in moist soil they commence to absorb moisture until the plant cells regain their former turgidity. The only possible advantage to be gained by this method, so far as I can see, is that in the process of absorbing moisture the cuttings swell somewhat and thus tighten themselves in the soil. Even when great care is taken an indifferent "strike" frequently results, and this is especially noticeable when the growth is soft and sappy, as is the case after a wet season such as we have experienced this year.

Quite recently I have discovered that *Pelargoniums* may be rooted in a far more certain and expeditious manner. It is the practice here to root cuttings of all such soft-wooded plants as *Ageratum*, *Petunias*, *Iresine*, *Coleus*, *Marguerite*, *Heliotrope*, etc., in close propagating cases, the rooting medium being clean, sharp, silver sand. In September we inserted several distinct lots of zonal *Pelargoniums*, and one batch in particular was extremely sappy, the plants from which the cuttings had been obtained having been grown in a shaded, moist, situation in an enclosed garden. They were given exactly the same conditions as the other occupants of the house, that is, they were shaded from bright sun and sprayed over during bright weather. The sand was kept constantly moist and the atmosphere heavily charged with moisture. The temperature of the house was always high, and in sunny weather it often reached 100° F. In ten or fourteen days from the time of insertion the cuttings were well rooted and ready for potting. After this potting it is essential to place them in a warm, close, house for a few days until they take hold of the new soil, when they may be moved to cooler quarters with safety.

Of a large number of cuttings almost one hundred per cent. rooted and at a time no bottom heat was available.

I have seen cuttings taken from stock plants in the spring treated in this manner with great success, and as it appears to possess decided advantages over the better-known British method, I certainly think it is worthy of trial by those whose business it is to propagate large numbers of bedding *Pelargoniums* and who have the necessary conveniences. *T. H. Everett, New York, U.S.A.*

ORCHID NOTES AND GLEANINGS.

BUTTERFLY ORCHIDS.

THE singular appearance of its flowers has always invested *Oncidium Papilio* with more than ordinary interest. The specific name is apt, for if an inflorescence be held in the right position, the floral resemblance to a butterfly is very striking, while the bizarre colouring intensifies the similarity between flower and insect.

The flowers are solitary but produced suc-

cessively from the same peduncle by elongations of the joint immediately below the ovary; the linear dorsal sepal and petals, slightly dilated at the apex, and three to four inches, or rather more, in length, are dull, brownish-red on the face and yellowish-green at the back. The lateral sepals, decurved and undulate, are bright chestnut-red, with transverse yellow markings. The three-lobed lip has small side-lobes, rounded, yellow and spotted with red, while the anterior

DAMAGE TO SITKA SPRUCE IN BRITISH COLUMBIA.

In *The Gardeners' Chronicle* of July 29, 1922, page 70, a communication from me was published describing the effects of a blight which in the winter of 1919-20 injured and killed many of the Sitka Spruce trees along the water front,

their foliage, but on Shelter Islands, a small, rocky group of some forty acres extent, situated about two miles east of Amphitrite Point, where all the trees are Sitka Spruce, the blight must have been more severe, for practically every tree is dead, and some were grand, rugged specimens which to all appearance had lived for several hundreds of years. I enclose photographs (Figs. 213, 214 and 215), taken by me on September 26, of portions of Mr. Jansen's Island, the largest of the Shelter Island group, and twenty-two acres in extent, which, with the exception of a cultivated acre or so in the south end, is original forest. The illustrations give some idea of the catastrophe, as all the trees shown, except four or five spindly saplings, are dead.

The first demonstration on record of this particular type of blight was in Stanley Park, near the city of Vancouver, a hundred miles east of us, when the foliage of the Sitka Spruce was injured there in 1913 or 1914.

There was a third outbreak noticeable in Ucluelet on August 20, 1922, when the foliage of both young and old trees turned brown as if infested by red spider.

Some idea of the extent of this third injury, geographically, was obtained from Mr. Bevan, C.E., who at the time reported its presence as very evident all along the water-front of Quatsino Sound, a hundred-and-sixty-five miles west of us, and now Mr. W. F. Gibson, who is commercially interested in Sitka Spruce, and has returned from a visit to Kyuquot, half-way between here and Quatsino Sound, reports that in some situations along the water front in Kyuquot Sound and westward, more than half the trees are dying or dead.

As a result of my former communication in *The Gardeners' Chronicle*, the Forestry Branch of the Department of Lands for British Columbia collected specimens, in 1923, from the injured trees in this district, and on examination inferred that the injury was the work of an aphid described in 1919 by Mr. Wilson as *Lachniella Vandykei*, Wilson, from material collected in Washington by Dr. E. C. Van Dyke of the University of California, on Tideland Spruce.

No doubt there are all kinds of insects on

FIG. 214.—DEAD SITKA SPRUCE TREES; SOUTH-WEST SIDE OF JANSEN'S ISLAND, BRITISH COLUMBIA.

lobe is sub-orbicular, large and yellow, with a broad, marginal band of red.

This remarkable and very handsome Orchid was introduced from Trinidad in 1824, by the then Governor, Sir Ralph Woodford, and the first flower has produced in Colville's Nursery, at Chelsea, during the following spring; a fine form is that known as *majus* or *giganteum*—a glorified variety.

O. Kramerianum differs from the foregoing species in its more orbicular and generally smaller pseudo-bulbs (the pseudo-bulbs of *O. Papilio* are oval-oblong or sub-orbicular, usually one-and-a-half-inch to two inches long, compressed and wrinkled), shorter and less profusely spotted leaves (the broad, coriaceous leaves of *O. Papilio* being dull green and mottled with purplish-crimson). The peduncles are shorter, while those of *O. Papilio* become two feet to four feet long under congenial conditions. The floral colouring is similar to that of its congener, but differently distributed. *Oncidium Kramerianum* was first detected by Warszewicz, in Ecuador, at 3,000 feet elevation, about the year 1852; the species was first flowered in the garden of Herr Jenisch, at Hamburg, after whose gardener, Kramm, it was named.

O. Limminghei has a close affinity with the aforementioned species; the chief superficial dissimilarity is the absence, or comparative absence, of elongation of the dorsal sepal and petals, while the leaves are usually procumbent. This *Oncidium* first flowered in the Botanic Garden at Liège, in 1855, the plants being sent from Caracao by the Dutch Consul of that port; the plant is dedicated to Comte Alfred Limminghe, a liberal patron of Belgian horticulture.

O. Limminghei is a very much smaller plant than *O. Papilio* and *O. Kramerianum* and, like those species, it will thrive in an intermediate temperature, in baskets or pans containing a compost of fibre and Sphagnum-moss.

When flowering in a public collection of Orchids, such as at Kew, Edinburgh and Glasnevin, the Butterfly Orchids invariably arrest attention, and when they are exhibited at either major or minor flower shows they create a great deal of interest. A. C.

for a distance of ten miles on each side of Amphitrite Point at the western entrance to Barclay Sound, Vancouver Island, British Columbia. I stated that along the immediate waterfront the trees consisted about equally of Sitka Spruce or Tideland Spruce (*Picea*

FIG. 215.—DEAD SITKA SPRUCE TREES; SOUTH SIDE OF JANSEN'S ISLAND, BRITISH COLUMBIA.

sitchensis), Cedar, *Thuja gigantea* and Western Hemlock (*Tsuga Albertiana*, syn. *heterophylla*), but only the Sitka Spruce were injured and killed.

Since then, in the vicinity of Ucluelet, where I am writing, the younger trees have regained

the West Coast Spruce, but the catastrophe on Shelter Islands would appear to be due to other causes. *Polypodium Scouleri* is not damaged, and the luxuriant undergrowth of *Gaultheria Shallon* is unharmed. Geo. Fraser, Ucluelet, B.C.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C. 2.

Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.

Urgent Communications.—If sent by telegraph, these should be addressed "Gard. Chron.," Rand; or by telephone, to Gerrard, 1543.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Letters for Publication as well as specimens of plants for naming, should be addressed to the EDITORS, 5, Tavistock Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

NOMOCHARIS.

THE many clever gardeners to whom the cultivation of the *Nomocharis* genus is a perplexing problem will be interested in the reproduction (Fig. 216) of a photograph Mr. Kenneth McDouall has kindly sent me of a colony of *N. Mairei*—as the old *N. pardanthina* of the Tali Range is now called—in his garden at Logan, in Wigtownshire. The plants have been raised from home-saved seeds and are now three years old; like those of the older colony in the same garden, which have already been referred to in *The Gardeners' Chronicle*,* they are growing in deep loam, which, if not always moist, is never dry; at the same time it is thoroughly drained.

The older colony has been established since 1921, when bulbs raised from seeds of Farrer's collecting in 1919 were planted out. These bore their first flowers in 1922,† and have bloomed annually since then. Latterly, self-sown seedlings have appeared. Mr. McDouall tells me that during the past summer one of the old plants reached a height of four-and-a-half inches short of five feet, and bore fourteen blooms, with fruit into the bargain—a remarkable feat for a species whereof the bulb is no larger than that of *Lilium tenuifolium*. Evidently, in its way, this *Nomocharis* responds to cultivation as well as *Lilium auratum*, for like that Lily in its native hills, wild plants of *Nomocharis* are not usually prodigal of flower. Uni-flowered specimens predominate, and those with three or more flowers are rare. It is as well that in this country the bulbs of *Nomocharis* do not go down so deep into the ground as the stem is high, like the bulbs of the wild *Nomocharis* described by Mr. Cox in *Farrer's Last Journey*,‡ though the fact that seedlings may be found at the bottom of the pan shows that they have not altogether lost their burrowing habit.

The success of the Logan experiment should encourage other gardeners to persevere in the cultivation of this baffling genus, and though, for reasons unknown to us, the conditions on the west side of Wigtownshire are obviously favourable to the acclimatisation of *Nomocharis Mairei*, it is not to be supposed that it cannot be cultivated elsewhere in Britain; indeed, it is known to grow in very different surroundings, as in Mr. Harley's garden in Perthshire, for instance, and at the Edinburgh Botanic Garden. To anyone who gives a moment's thought

to the subject, these two places might seem likely to be rather more favourable to the growth of a genus of which the natural home lies at about the 13,000 feet level on the alps of Western China, than the shore of the Mull of Galloway; but the fact that *Nomocharis* flourishes in surroundings so utterly different from those in which it grows naturally is of good augury for cultivators. Incidentally, it affords but one more instance of the amazing adaptability of plants.

A point about the *Nomocharis* at Logan is that Mr. McDouall finds no trace of the stoloniferous habit of the stem which Mr. Forrest has often noticed in wild plants of *N. Mairei*.

There seems no doubt that, like most Lilies, *Nomocharis* is a sun-loving genus, though rain can have no terrors for them, as they come naturally into bloom in the rainy season, hanging their heads normally, but lifting them up whenever the sun breaks through the clouds. It might be worth while to try a few bulbs in a meadow where *Fritillaria Meleagris* is established. A. Grove.

FIG. 216.—NOMOCHARIS MAIREI (*N. PARDANTHINA*) IN MR. McDOUALL'S GARDEN AT LOGAN.

CHILI AND THE ANDES.

No. III.—ON THE WAY.

THE run from Havana to Cristobal, the Atlantic port of the Panama Canal, occupied four days. We landed in late afternoon, and went straight out to see the famous Gatun Locks and Spillway, a seven or eight miles run of extraordinary beauty and interest. The country is hilly and densely clothed with rank tropical forest, and we caught glimpses now and then of winding lakes and lagoons lying in the hollows. On the higher ground were colonies of the dwellings of the canal workers, neat and trim, in well-kept, unfenced gardens, and looking like meat-safes, with every door and window securely gauzed against flies and the deadly mosquito. The soil everywhere was a livid red colour and contrasted strangely with the rich green vegetation. For a mile or two the road ran close to the old original canal of de Lesseps—a sad, abandoned failure it looked beside its highly

successful Yankee successor, yet it was beautifully picturesque, its waters stained a deep orange by floods, and its banks festooned with every sort of fantastic tropical glory.

I had always vaguely imagined that the Panama Canal consisted of one great continuous ditch from the Atlantic to the Pacific, and it was only when I viewed it from the Gatun Locks, which lie a few miles in from the Atlantic entrance, that I realised that the central portion of the canal is not a canal at all, but an artificial lake. The engineers constructed a dam, 8,000 feet long and 2,600 feet wide, and thus flooded a tract of country and converted it into a vast lake. The overflow from the lake is near the Gatun Locks, a terrific Spillway whose water-power generates the electricity by which the locks are operated and the whole district lit.

The gently undulating slopes of the Atlantic side of the Gatun dam have been converted into a fine golf course, across which we walked from the locks to the Spillway. The greens were in beautiful order, and appeared to be produced by frequent sowings of seeds. The grass had a fresh, young, impermanent, look. In the fairways it was interesting to see growing two plants not usually associated with golf courses—a *Selaginella* and the Sensitive Plant (*Mimosa pudica*), the latter mown or rolled to a prostrate habit. Here, too, we watched the leaf-cutter ants at work, each ant carrying a slab of green leaf very much bigger than himself, or a length of green grass, almost an inch long and carried upright. They were marching upon regular roads which they had made across the turf, hard and smooth, several inches wide, leading to their underground habitations, the entrances to which were like miniature craters. The cut leaves and grass are carried below and stacked into what might almost be called hot-beds, or Mushroom-beds, on which the ants cultivate a species of fungus which they use as food. These leaf-cutter ants often do terrible damage to crops, cutting the plants to shreds.

Near the golf course we found trees of *Cecropia*, and were able to study the fierce little ants who inhabit the hollow stems of this tree, and defend it from the attacks of the leaf-cutter ants. In the wall of each hollow internode of the stem is a thin spot, and in each of these thin places the ants make a hole, into and out of which they can pass. We snapped several stems, and instantly the tiny ants rushed out and dashed around, very angry. The *Cecropia* produces food bodies at the bases of its leaf-stalks, on which the defending ants feed. We noticed one or two young *Cecropia* trees whose leaves were very ragged and had been much cut about, and in every instance we found, on testing them by snapping the stems, that no ants rushed out. Evidently something had happened to the defending army, and the leaf-cutters had taken the opportunity of robbing the leaves. Every *Cecropia* which we examined whose stems were inhabited by the tiny, defending ants, had perfect leaves, untouched by leaf-cutters.

In a few of the gardens of the canal zone we noticed an exceedingly handsome flower, a Composite, probably an annual, and looking much like a *Cosmea*. This grew from three to four feet high, and the flowers, very solid in texture, were a superbly rich orange colour. We saw the same thing as a cut flower at the Washington Hotel that evening, and made urgent enquiries as to what it was, or when seeds could be obtained, but got nothing but vague negatives. Late that night, just as we were going on board, panic thoughts of that orange *Cosmea* held us, and in a tiny trap we ambled back to the Washington to make our last effort to secure a seed, or news of where a seed might be had. It was very late, but we found and interviewed a really very important hotel official, who, however, was a perfect miasma of vagueness. Finally, we raided the hotel garden, and by a reckless display of matches discovered not only a bed of orange "*Cosmea*" in flower, but a few reasonably small seedlings, which we dug up and carried off. Our idea was to nurse these through to Valparaiso, where, in a garden, they were to flower and produce seeds to send home to England. They were all dead in three days!

* February 5, 1927, p. 99.

† Not 1923, as reported in *Gard. Chron.*, Feb. 5, 1927, p. 99.

‡ p. 89 (1926).

Next day we passed through the canal. It was, of course, intensely interesting, but this is not the place to write of an engineering triumph. I cannot refrain, however, from remarking on the superb organisation which takes great ocean liners through those immense locks, lifts them some seventy odd feet in a few minutes, and passes them quietly out into the lake above, without a shout, with scarcely a word spoken, and with barely a drop of water splashed. The locks are in a setting of trim, shaven lawns. The authorities charged, I was told, between two and three thousand pounds for taking us through the canal, but they did it handsomely and with consummate efficiency.

The lake section of the canal is extremely picturesque. The country is, in contour, rather like the Trossachs, but the low, rounded mountains are clothed in dense tropical jungle, and the lake goes winding away for miles in deep romantic inlets between the hills and is further broken by countless islands, large and small. When the lake was made, by flooding, thousands of trees which originally grew on dry land found themselves standing in the new water, some half submerged, others up to their knees, so to speak, and there they still stand, dead and drowned, melancholy skeleton trees, with strange epiphytic plants clinging to their trunks, and small, grey pelicans perching on their rotting branches.

The last section of the canal, the Culebra Cut, gave us an interesting view of its vegetation and its fauna at close range on either bank as we sweltered slowly through. A Musaceous plant, looking like a giant *Strelitzia*, with splendid scarlet flowers, grew in enormous clumps at the water's edge. White egrets and a charming little blue heron trotted upon the shore, fearless alike of basking alligators and of passing ships.

Numbers of gaudy, sensational-looking hornets visited the ship, and now and then a splendid butterfly would flaunt across the decks. The heat was terrific, oppressive, in spite of zephyr clothing, electric fans and lunch served on the shady deck, with iced drinks, cooling fruits and sprightly music from the ship's orchestra. I found that the best way to endure the overwhelming swelter—at which some folk were inclined to wail—was to picture the first early Spanish conquerors hacking their way across this same isthmus on foot in steel armour. Stout fellows those old Spaniards! *Clarence Elliott.*

TREES AND SHRUBS.

RHODODENDRON SOULIEI.

THIS evergreen *Rhododendron* (Fig. 217) is a native of Western China, where, apparently, it covers large areas at an altitude of from 9,000 to 10,000 feet. It was introduced to this country in 1905 by Mr. E. H. Wilson, when collecting for Messrs. J. Veitch and Sons.

Free of growth and of good habit, it forms a fairly compact bush, three or more feet in height, the young growths being purplish, and covered with glands which exude a sticky substance. The leaves are quite attractive, being broadly-ovate in shape, from one-and-a-half inch to two-and-a-half inches long and one inch to two inches wide, with heart-shaped base and bluntly-pointed apex; they are glaucous-grey, smooth on both surfaces, and have short, glandular stalks.

The flowers of *R. Souliei* are produced during early May in terminal clusters of five or six, and they are a pale rose-pink colour. The corolla is saucer-shaped, usually five-lobed and about two-and-a-half inches in diameter.

Rhododendron Souliei usually produces its beautiful blooms with freedom, and it is quite hardy, so that it is a useful addition to our gardens, flourishing under conditions usually provided for *Rhododendrons*. *A. G. F.*

EUONYMUS EUROPAEUS.

A NATIVE shrub which can bear comparison, when in fruit, with many of the new introductions from Asia and elsewhere is the Spindle-tree (*Euonymus europaeus*). It is found in copses and hedgerows, chiefly in England, and more

rarely in Scotland and Ireland, mainly on chalk or limestone formations. In its wild state it forms a bush ten to twelve feet high, but under suitable conditions it will make a tree up to twenty feet high.

It is a deciduous shrub, bearing oval to lance-shaped, glossy leaves, in pairs; when bruised, these give off a foetid odour, and the juice is said to be poisonous. The leaves have finely-toothed margins. The young twigs are green and four-angled, while the older wood is covered with smooth, grey bark, and in old specimens the trunk is usually furrowed longitudinally.

Celastrus Order, and is thus closely related to the climber *Celastrus articulatus* which fruits in the same fashion. *L. Le C. T.*

AZARA MICROPHYLLA.

AZARA microphylla may well be considered one of the most attractive shrubs in cultivation in this country because of its extremely graceful habit of growth. Although a native of Chili it may be grown in the open in most districts, provided it is not placed in an exposed position. In warm districts it attains the dimensions of a small tree, from twenty to thirty feet in

FIG. 217.—RHODODENDRON SOULIEI.

In the early part of the year the Spindle Tree may be confused with the Dogwood or Buckthorn, but in autumn, when the leaves have turned red and yellow and the fruits are ripe, there can be no doubt as to its identity. The flowers are small and greenish, borne in considerable numbers in loose cymes in May and June. The fruits are three to five-lobed and deeply grooved along the lines of division. The case itself is pale crimson, and each seed is wrapped in a bright orange arillode or envelope, providing a sharp colour contrast.

This shrub, if better known, would find a welcome in many gardens, with the other members of its family. It belongs to the

height, but usually forms a handsome bush about ten feet high, while in cold districts it requires the protection of a wall, a position for which it is admirably suited owing to the regular branching of the growths.

The slender branches are densely clothed with blackish down and thickly furnished with small, glossy, deep green leaves which are obovate in shape and usually have toothed margins. They are produced in pairs, the outer ones being much larger than the inner, which are more rounded. The flowers—the insignificance of which is amply compensated by their strong Vanilla fragrance, which can be detected some distance from the plant—are produced

during February and early March in small clusters in the axils of the leaves.

There is a variegated form of this beautiful shrub which makes an attractive wall plant and seems to retain its variegation with age, the leaves being heavily marked with yellow.

Azara microphylla is fairly rapid in growth if planted in good loamy soil, and is propagated either by layering or by cuttings of ripened shoots inserted in a cold frame during autumn. *A. G. F.*

ERICA CILIARIS VAR. MAWEANA.

This is undoubtedly the finest of the Dorset Heaths, and a plant which stands out above all other late-flowering, dwarf Ericas. It was discovered in Portugal by the late Mr. George Maw, rather more than fifty years ago, and may be distinguished from the typical *E. ciliaris* by its shorter, more upright growths, by the darker green of its less glaucous foliage and more bushy habit. It is not so inclined to trail as the common Dorset Heath, and the flowers are a good deal larger, being fully half-an-inch long and proportionately wide. In colour they follow the type closely but are a somewhat deeper, and more crimson purple. This fine Heath is quite as hardy as the typical species, and with me it does very well in a moderately cool, freely-drained, lime-free loam. The flowering season extends from early August until November. *A. T. J.*

THE VALUE OF DECORATIVE FOLIAGE IN WINTER.

THAT foliage plays an important part in decorative gardening cannot be gainsaid, for even in summer our displays of flowers are incomplete without accompanying foliage, while foliage plants serve as a back-ground to many floral schemes, and greatly enhance the beauty of them.

In winter, when most outdoor flowers have vanished, foliage is the chief source of beauty in the garden. A stately Yew hedge is an admirable set-off to a large flower border in summer, and in winter it remains a thing of beauty. The Hornbeam or Beech hedge, with its totally different shade of green in summer, and its rich brown tone in winter has attractions at both seasons, and the foliage of a well-grown Holly hedge is a delight all the year round.

In the planting of deciduous trees and shrubs for permanent effects, the introduction of groups of subjects with coloured foliage to contrast with the green foliage of other kinds is of great assistance in rendering the shrubbery attractive after the majority of its occupants have passed their flowering stage. There is a large number of plants suitable for this purpose, and when planting one may visualise the rich red of *Prunus cerasifera* Pissardii and *Acer palmatum sanguineum*; the deep purple of *Corylus Avellana purpurea* and *Rhus Cotinus purpurea*; the bright yellow of *Acer Negundo aureum*, *Catalpa bignonioides aurea*, *Ribes aureum*, *Sambucus nigra aurea* and *Cornus alba Spathii*, and the silvery tones of *Acer Negundo variegata* and *Cornus alba variegata*.

But probably the evergreen trees and shrubs appeal most strongly to planters because of the important part they may be made to play in the winter landscape, and in this direction the Conifers are extremely valuable and offer a wide choice of subjects with golden, silver, grey or glaucous-tinted foliage.

The genus *Cupressus* is rich in golden and silver foliated varieties, of quick growth and graceful habit, and many of the *Lawsoniana* group are particularly attractive. *C. L. lutea*, *C. L. Westermanii aurea*, *C. L. Stewartii* and *C. L. Hillieri* are all excellent golden plants. *C. L. Allumii* is one of the best "blue" varieties, of true conical shape and rich glaucous colour; *L. C. Triomphe de Boskoop* is of rather looser habit, and *C. L. Fletcherii* is a distinct, compact-growing variety with silvery-grey foliage. *C. lusitanica argentea* has very beautiful silvery-grey foliage, and *C. macrocarpa lutea* is a golden tree of remarkably quick growth. *C. (Retinospora) obtusa* has several golden varieties of

merit, of which *Crippsii* is a beautiful plant of elegant habit. *C. pisifera* has also varieties of a good yellow colour, notably *filifera aurea* and *plumosa aurea*.

The genus *Taxus* also provides several elegant shrubs with golden and silver foliage. *T. baccatus elegantissima*, *T. b. semperaurea* and *T. b. Standishii* are excellent golden varieties, while *T. b. alba variegata* and *T. canadensis Washingtonii* are good silver varieties. The Irish Yew has gold and silver forms in *T. b. fastigiata aurea* and *T. b. f. argentea* respectively.

Many of the *Abies* are noted for their silver foliage, and they are commonly known as the Silver Firs. *A. concolor*, *A. c. candicans*, *A. lasiocarpa coerulescens*, *A. nobilis glauca* and *A. Pinsapo glauca* are noteworthy for their glaucous tints. Some of the *Piceas* are probably the richest of all in bluish-grey shades. *P. pungens argentea* being a strikingly beautiful plant, while *P. p. Kosteriana* and *P. p. Moerheimii* make fine specimens of an intense blue colour, beautiful when grown as isolated specimens, and still more beautiful when planted in conjunction with other evergreens which tend to accentuate their depth of colour.

Several other Conifers of considerable merit may be added to the material available for winter-colour schemes. Junipers include attractive golden and silver varieties. There are several *Thuyas* with rich golden foliage and some of the species of *Pinus* have more or less light-coloured foliage of a glaucous tint which contrasts with that of darker hue, while *Pseudotsuga Douglasii glauca elegans* and *Tsuga Pattoniana glauca* are two fast-growing Conifers, which soon make beautiful and graceful trees of a delightful soft grey shade. *Cryptomeria japonica elegans* is of distinctly ornamental value, the bright green foliage of summer turning to an attractive reddish-brown in winter.

Important as the Conifers are, however, in any planting scheme where winter-colour effects are the influencing factor, they by no means exhaust the list of suitable subjects for such purposes, for there is almost as wide a choice in other plants, mostly of a shrubby nature.

Ilex Aquifolium, the common Holly, has numerous golden and silver varieties which carry their brilliant colour throughout the winter; well-grown specimens of Golden King and Silver Queen are objects of outstanding beauty, useful in almost any position, while there are weeping forms of both varieties. The variegated forms of *Aucuba* are useful for winter colour, and grow freely even in the partial shade of other trees, though the colour is then less intense. *Eleagnus macrophylla* has attractive, silvery foliage and *E. glabra folio-aurea* is one of the most beautiful evergreen, golden-leaved plants we possess. *Euonymus japonicus* provides both golden and silver varieties of considerable merit, while *E. radicans variegata* is an excellent silvery-leaved prostrate shrub for positions where only dwarf plants may be used.

Cassia fulvida (*Diplopappus chrysophyllus*) is a quick-growing plant of graceful habit with attractive, golden, Heath-like foliage, while of *Buxus sempervirens* there are golden and silver varieties. Even the much-maligned Golden Privet, *Ligustrum ovalifolium aureum*, rapacious as it is, is well worth growing for colour effect, and well-trained, rounded heads produce golden balls of an intensity of colour which few other plants can equal, while massive groups are very telling for distant effects.

There is a host of grey, silver and glaucous-tinted shrubs, many of which retain their attractive colour and are highly decorative subjects throughout the winter. The soft grey of the Lavender—*Lavandula spicata*; the intense silvery colour of the Cotton Lavender—*Santolina incana*; the subdued grey and green of the Rosemary—*Rosmarinus officinalis*; and the almost glaucous blue of the Rue—*Ruta graveolens*, are well-known, and all have their attractions. Many of the *Artemisias* have bright, silvery foliage and are very attractive, their colour being particularly good on light, dry soils. Several of the *Senecios* are also excellent grey-leaved plants, *S. Greyii* being probably the best of all, while *Phlomis fruticosa*, which succeeds in the poorest of soils, has effective,

grey foliage. Other plants attractive because of their grey or glaucous foliage are species of *Atriplex*, *Cistuses*, *Olearias*, *Teucriums* and *Yuccas*.

Finally, the grasses include many highly attractive foliage plants, most of which are at their best during the late summer and autumn, but some of them carry their beauty well into the winter months. *Gynerium argenteum* is a strikingly effective plant in the autumn and early winter months, and bold masses by the water-side or on drives are highly decorative. *G. a. aurea lineata* is a handsome variety with rich, golden-striped leaves, and makes a fine lawn specimen. *Elymus glaucus* is a fine grass with almost blue foliage. *Eulalia japonica variegata* with foliage richly striped with silver, and *E. j. zebrina*, its deep green leaves carrying rings of yellow bars, are very effective plants that remain attractive through the winter but lose their lustre in the spring, when they should be cut down before they commence to grow again. *Glyceria spectabilis folio-variegata* is a golden-striped grass of brilliant colour and a rampant grower in a moist spot. Among other grasses that provide richly-variegated or striped foliage there are species of *Dactylis*, *Festuca* and *Phalaris*. The *Phormiums* are, unfortunately, not hardy everywhere, but they are amongst the most distinct and effective foliage plants we have, their handsome, glaucous leaves being attractive at all seasons, and they should be grown in favoured localities. *A. P. C.*

AUTUMN FOLIAGE.

At the autumn season of the year brilliantly coloured foliage attracts the eye on all sides. The Maples, Hickories and other trees, whose leaves colour early, have shed their foliage, but the Oaks, the noblest group of trees in eastern North America, were at the height of glory very much later this year than is usual. The Scarlet, Red and White Oaks take on ruddy tints varying from reddish-purple and crimson to red. The Black and Swamp Oaks develop imperfect shades of orange to leather-brown tints. All the Oaks hold their autumn-coloured leaves longer than other trees and often we enjoy their colour from mid-October to mid-November. Where deciduous-leaved trees are associated with Conifers, the landscape effect in the autumn is immensely heightened. The contrast between the brilliantly tinted foliage on the one hand and the dark green of the Conifers on the other is very impressive.

One is often asked the why and wherefore of autumnal tints—a simple question not easy to answer, but briefly the metamorphosis is effected as follows: At the approach of winter, leaves, which cannot withstand frost, cease to function as food factories, and the residue food substances are conveyed from the leaf-blade into the woody branches and there stored, chiefly in the form of starch, until the season of growth recommences the following spring. The leaves from which everything useful has been transported form nothing more than a framework of cell chambers containing waste products, such as crystals of calcium-oxalate, which are thrown off with the leaves and help to enrich the soil. But while the process of food evacuation is going on other changes take place.

In many plants a chemical substance, known technically as anthocyanin, is produced in the leaves and often to such an extent as to become plainly visible on the exterior. In the presence of free acids in the cell-sap it appears red, blue when no acids are present, and violet when the quantity of acids is small. In a great many leaves the chlorophyll bodies, which contain the green colouring matter, become changed to yellow granules. Sometimes these yellow granules are few and anthocyanin is absent, then the leaf, except losing its freshness, exhibits little outward change before it falls. In others the yellow granules are abundantly developed, and if anthocyanin is absent or nearly so the whole leaf assumes a clear yellow hue. If there is an abundance of yellow granules together with free acids and anthocyanin the leaf assumes an orange colour. Thus the leaf

at the period of autumnal change by the presence of these substances in a greater or lesser degree loses its green hue and becomes brown or yellow, crimson or orange, purple or red. From the "Bulletin" of the Arnold Arboretum.

THE CLAY-COLOURED WEEVIL.

THE Clay-coloured Weevil (*Otiorhynchus picipes*, F.) is one of our most serious plant pests; in common with most of our coleopterous pests, it does harm during two stages of its life history, the adult weevil feeding upon the aerial parts of many plants, and the larval stage feeding upon the roots of a wide range of subjects. The double damage it is capable of is rather important, because we are so apt to take notice of the more obvious trouble and overlook the more obscure workings of this weevil. The damage done by the adult weevil is, of course, frequently noticed, simply because it can be seen on the aerial parts of the host plant, but the larval damage to the root system is frequently overlooked altogether.

Two other features also qualify *O. picipes* as a serious pest. One feature is that the insect is very generally distributed, while the second is that it is a general feeder. The weevil is common in all types of soil, and it is certainly not confined to gardens; it may be found in the pleasure grounds, parks, woods, fields and hedgerows, and seems equally happy in all. With regard to its feeding habits, it would seem almost the easier plan to list those plants it has not been recorded as feeding upon. The adult weevil will eat the aerial parts of most fruit trees and shrubs, and is also recorded as feeding upon many kinds of vegetables and some field crops. I assume that the larval stage can feed on almost any kind of root.

Damage by *O. picipes* is perhaps mostly noted on Raspberries, Loganberries, Roses and worked nursery stock, and the damage is often serious upon Red Currants, the Flowering Currant and Apple trees. Fruit trees of all kinds trained upon walls often receive a good deal of attention, especially if the walls have many crevices which serve as hiding places during the day. Ornamental shrubs are favourite hosts of this weevil, and all kinds of Rhododendrons as well as the Cherry Laurel (*Cerasus Laurocerasus*) are very prone to attack; the damaged foliage of these puzzled me for a long time, but a chance look beneath some clods of soil near some disfigured Rhododendrons revealed *Otiorhynchus picipes*. Since then, I have examined very many Rhododendrons and Cherry Laurels, and whenever damaged foliage has been found by day, these weevils may be found at night. Weevils collected and brought home and fed with whole Rhododendron or Laurel leaves produced the same type of damage.

The life history of *O. picipes* is as follows:—The adults appear in spring and at once commence to feed upon the various host plants. Towards the end of the summer the females begin to deposit their eggs in the soil beneath the plants upon which they are feeding. The eggs are small, round, and of a whitish colour when newly laid, but they turn a very dark brown before hatching; under artificial conditions the incubation period appears to be about twenty-one days. The grubs are white with hairs scattered over the body, and the head is brown, and the mouth parts shaped for biting; this stage of the pest lasts throughout the winter, and the grubs may be found in the soil, lying in a curved position, and appear to have very limited powers of locomotion.

When fully grown, they measure up to a quarter-of-an-inch in length, and when this period is reached the grubs make an earthen cocoon very near the top of the soil. In this earthen cocoon they change to creamy-white nymphs, and all the parts of the adult weevil can be clearly seen. In captivity the nymph stage occupies about three weeks, but may be speeded up by keeping the specimen under warmer conditions, which rather points to the fact that soil temperature would have a good deal of influence upon the length of the pupal stage.

It is recorded that the adult weevils may be found so early as April, but that the majority appear in June and July; this may be due to the fact that after the egg-laying period many of the adults hibernate for the winter. I am of the opinion that the early specimens are those left over from the previous year and which have sheltered for the winter. The majority mentioned above as appearing in June and July are in the main the new generation. I find that many adult *O. picipes*, collected in July and fed upon Apple foliage so long as it could be obtained will live all the winter, and will commence to feed upon young Apple foliage so soon as it can be obtained in the spring; whether or no these over-wintered adults are capable of laying another batch of eggs, I have not yet been able to determine.

The control of this weevil presents many difficulties to the gardener. In the case of the adults, trapping in some form or the other seems to be most successful. Advantage should be taken of the fact that they feed at night and hide by day. I find that my best results are obtained by breaking up all lumps of soil beneath the attacked plants and then putting hay-bands around the collars of plants which lend themselves to this treatment. In other cases, heaps of hay are placed as near to the infested plants as possible. The hay-bands, or hay-traps, are examined daily if time permits, and in any case not less than twice a week. The weevils are collected by hand and destroyed.

I once had what I thought to be a great idea. *O. picipes* was doing a great deal of damage to the leaves and flowers of some standard Apples, and my idea was to put a grease band in position so that the weevils would be trapped when crawling up the branches; but it would appear that I had very much underestimated the intelligence of this weevil, because although I used many grease bands, never once did I trap a weevil. I thought at first that my failure was due to the fact that when weevils are feeding on this class of subject they do not descend to the soil, but hide by day in the bark crevices, until darkness comes again. To get over this difficulty, I cleared a tree to the best of my ability of all weevils, and I was surprised to find that I still caught none on the bands. At the same time, the damage to the tree practically ceased, which indicated that I had shaken down most of the weevils and no more were going up. If the fact always holds true that *O. picipes* will not cross a grease-band, it should be a good control to put such a band in position before the attack starts. This, of course, is only possible on a few of the host plants favoured by this weevil. Many other trials, too, would be necessary before one could state such a fact with any degree of certainty.

The larval stage, when it takes place upon certain host plants, lends itself rather well to control measures. Under all conditions, where a good soil insecticide can be worked into the soil during early spring, it should be possible to kill many larvae. I have used naphthalene at the rate of two ounces per square yard with a good deal of success in this connection. A set of conditions where this method is useless is where potted plants are infested with the grubs of *O. picipes*. I have a case in mind where some thousands of various rock plants potted in three-inch pots were badly infested with grubs. The only control measure short of burning the stock was to shake out the plants and destroy the grubs, but some rock plants resent root disturbance, apart from the labour involved. We are badly in need of a fluid which could be used to kill this class of grub without injuring the growing roots, and at the same time at a price to allow of economic application.

The pupal stage of *O. picipes* is the weakest stage in its whole life history, and it is probable that a soil insecticide, as mentioned above, in connection with the larval stage, if used during the pupal stage would help to control the pest. Soil cultivation during this delicate pupal stage would destroy many, for the slightest touch seems to injure the nymphs, and as they are mainly situated in the top two inches of soil, the Dutch hoe should be used freely, especially beneath shrubs. Somerset.

NOTES FROM WISLEY.

ALTHOUGH the recent combination of frost and fog may have kept many garden lovers indoors, the charm of the garden has by no means been completely eclipsed. Under such conditions new effects are produced. For example, the blotting out of certain well-known features may give prominence to others which have been overlooked, and may form a hitherto unrecognised picture. The appearance of the plants themselves also is in many cases completely altered, and their character is emphasised in a pleasing way by the hoar frost which clings to the foliage.

In the fog and frost which prevailed when I last visited Wisley some of the most attractive effects of this nature was noticed among the Berberis hybrids belonging to the Wilsonae and polyantha groups. Their coral berries positively glowed in the grey fog and were considerably enhanced by the rime-edged foliage.

Under glass at Wisley there is a good show of Fuchsias, among which large-flowered varieties such as the double Lima and Try-me-on, with its large, skirt-like corolla, are conspicuous. Another variety which is blooming profusely and whose blooms, if not individually striking, are most attractive when seen collectively, is Cupid, with deep rose calyx lobes and a mauve corolla. Fuchsia parviflora, a native of Mexico, with small leaves and tiny, red flowers, is also in bloom, while the even more curious F. procumbens, whose greenish flowers are over, is now in fruit, and bears numbers of rather large, oval, red berries covered with a glaucous bloom.

In the alpine house several hybrid Saxifrages belonging to the Kabschia section are showing their first flowers, including S. Lady B. Stanley, and S. Brenda, with pretty pink blooms. A few of the earliest Primulas are also starting into bloom, such as P. megasaefolia, P. frondosa and P. Winteri. The plants of the last species which grow in the rock garden, however, are much further advanced than those in the alpine house. Other plants of interest in and around this house include Parochetus communis—the Blue Pea—Iris alata, a pretty, blue-flowered, bulbous species, and Viola arborescens, with flowers of very pale lavender and possessing a stiff and erect habit.

Still more improvements are being carried out in connection with the rock garden. Around the cave, the rock work has been altered and replanted over a large area. This considerably enhances the effect of a good specimen of Stranvaesia undulata which surmounts this section. The cave itself has not been touched and remains effectively draped with a number of spreading and climbing plants which form a dense, interlacing mass. They are composed of Lonicera, Cotoneaster horizontalis and Muehlenbeckia varians, which has wiry stems and leaves in the shape of a fiddle.

Another portion of the rock garden which is being altered is the bottom corner nearer to the Peach wall. The existing Yuccas and Junipers are being supplemented with new varieties and among them is an unnamed dwarf Juniper, lately received from Bonin Isle. A new path also is being made into the rock garden, an extension of the walk which runs from the Laboratory along the Peach wall. It leads through the outskirts of the wild garden, and the clearing of the ponticum Rhododendrons in the formation of the path has exposed to view a fine specimen of Ilex latifolia which has hitherto passed unnoticed. The leaves are of a similar shape and size to those of a Rhododendron, but the margins are serrated. It also bears red berries. Progress is being made with work on the piece of ground which is being developed by the river bank. This is a large, flat strip by the waterside and is composed of rich alluvial soil. Bamboos, such as Arundinaria japonica, A. anceps and A. nitida, have already been planted, and a large area will be devoted to Daffodils, for which this should be an ideal spot. There are many places here also which should favour the growth of bog Primulas, Japanese Irises and foliage plants, such as Rogersias and Gunneras, while the high bank at the back would look well planted with Rhododendrons and Azaleas. J. E. Grant White.

MESEMBRYANTHEMUM.

(Continued from p. 450.)

12.—GLOTTIPHYLLUM HAW.

12. G. angustum, N. E. Br., in *The Gardeners' Chronicle*, 1921, Vol. LXX, p. 327. Leaves linear—tongue-shaped, semicylindric, very long, 3–4 inches long and $\frac{1}{4}$ – $\frac{1}{2}$ inch broad according to Haworth, who described it from memory only (he subsequently gives no other dimensions). Flowers subsessile. Calyx very large and fleshy, 4-lobed, the larger lobes gibbous and keeled on the back. Corolla 3–4 $\frac{1}{2}$ inches in diameter, petals numerous, united at the base for about a quarter-of-an-inch, up to 2 lines broad, obtuse and obsoletely crenate at the apex. Stamens yellow. Stigmas 10, long. Capsule with 10 ridges on the top.

M. angustum, Haw., *Obs.*, p. 176 (1795), *Misc. Nat.* 34, *Syn. Pl. Succ.*, p. 222, and *Rev. Pl. Succ.*, p. 101, not of Berger nor other authors.

South Africa: Locality unknown, introduced by Masson in 1790, according to Aiton.

The above description, taken from Haworth's account of it, contains all that is known of this species, which is evidently quite distinct from any that has hitherto been figured and unlike any species I have seen, although *G. concavum* N. E. Br., must be near it. Haworth states that it can be "recognised at sight by its semicylindric leaves." The large flowers with the petals united for a quarter-of-an-inch at the base, however, distinguishes it from any other species at present known.

In his *Revisiones Plantarum Succulentarum* Haworth adds two varieties:—var. *pallidum*,

1–2 series, subacute or bluntly pointed at the apex.

Mesembryanthemum taurinum, Haw., *Syn. Pl. Succ.*, p. 224 (1812), and *Rev. Pl. Succ.*, p. 100 (1821); Berger, *Mes. und Port.*, p. 236. *M. angustum* var. *pallidum*, Haw., *Rev. Pl. Succ.*, p. 101. *M. angustum*, Salm Dyck, *Hort. Dyck*, 1818, p. 17, and *Mes.*, §7, Fig. 6; not of Haworth. *M. linguiforme* var. *angustum*, Berger, *Mes. und Port.*, p. 241.

South Africa: Locality and collector unknown. Fig. 218 is adapted from Salm Dyck's figure

Mesembryanthemum angustum var. *heterophyllum*, Salm Dyck, *Mes.*, §7, f. 6B, not of Haworth. *M. linguiforme* var. *heterophyllum*, Berger, *Mes. und Port.*, p. 241.

South Africa: Locality and collector unknown.

The above description is compiled and Fig. 220 adapted from Salm Dyck's figure above quoted as I have not seen any plant like it, for it is quite distinct from the plant Haworth called *M. angustum* var. *heterophyllum* (see 16, *G. longum* var. *hamatum*), differing conspicuously by its less hooked leaves, from which the elevated ridge along the lower margin of the larger leaf of a pair is apparently entirely absent, and by the sessile flowers.

16. G. longum, N. E. Br., in *The Gardeners' Chronicle*, 1922, Vol. LXXI, p. 9 (Fig. 221, p. 471).—Leaves more or less in two rank usually about 3 pairs to a growth, at first ascending and then spreading, or remaining ascending under some conditions, 3–5 (or in young plants up to 9) inches long, 7–11 lines broad and 3–4 lines thick, strap-shaped, usually somewhat curved, very obtuse, or here and there obliquely pointed or rarely slightly hooked at the apex, flat on the face, convex on the back, with the thickest part of the convexity usually nearer one margin than the other and sometimes forming an oblique keel at the apex, soft and pulpy in substance, smooth, glabrous, light green, shining, with a very evident paler and somewhat triangular swelling or pustule at the base on the upper side. Pedicels erect, $\frac{1}{4}$ – $\frac{1}{2}$ inch long, slightly compressed and about 3 lines thick, smooth, glabrous, green. Calyx 4-lobed, glabrous, green; lobes 5 lines long, the two outer about 5–6 lines broad and the two inner 3 lines broad, ovate, obtuse and more or less mem-

FIG. 219.—GLOTTIPHYLLUM UNCATUM.
Leaves adapted from a drawing at Kew.
Flowers pedicellate.

quoted above under the erroneous name of *M. angustum*.

14. G. uncatum, N. E. Br., in *The Gardeners' Chronicle*, 1921, Vol. LXX, p. 336 (Fig. 219).—Growths apparently prostrate. Leaves in two ranks, very spreading and slightly sloping downwards, 2–3 inches long and 7–8 lines broad, strap-shaped, more or less curved, flat above, obliquely convex beneath, with the apex of one leaf of a pair thickened and keeled on the back and slightly hooked or upcurved edgewise at the obtuse apex. Pedicels 6–9 (in fruit up to 12) lines long, compressed. Calyx 4-lobed. Corolla about 2 inches in diameter; petals in 1–2 series, acute, yellow. Stamens yellow. Stigmas 10, short, plumose, yellowish. Ovary globose, convex on the top.

Mesembryanthemum uncatum, Salm Dyck, *Mes.* §8, f. 6. *M. longum* vars. *uncatum* and *attollens*, Haw., *Rev. Pl. Succ.*, p. 97 (1821). *M. linguiforme* vars. *uncatum* and *attollens*, Berger, *Mes. und Port.*, p. 240 and 241.

South Africa: Locality and collector unknown. It was raised at Vienna in 1816 from seeds received from South Africa, according to Salm Dyck.

I have not seen this species. There is a good unpublished coloured drawing of it at Kew, made in 1823 from a plant received that year from Salm Dyck himself, from which Fig. 219 was adapted.

15. G. proclive, N. E. Br. (Fig. 220).—Growths more or less decumbent or prostrate. Leaves in two ranks, directed forward in the direction of growth, more or less sloping downwards and somewhat spreading or diverging, $2\frac{1}{2}$ –4 inches long, 6–7 lines broad at the middle and 3–5 lines thick, upcurved edgewise or by a slight twist at the obtuse apex, flat or slightly concave on the face, convex on the back, the larger leaf of each pair being somewhat compressed and keeled where produced beyond the flat face at the apex. Flowers sessile or subsessile. Calyx-lobes all flat and apparently with very broad membranous margins. Corolla about 2 $\frac{1}{2}$ inches in diameter; petals in two series, about one inch long, cuneately linear, obtusely pointed or notched at the apex, yellow. Stamens very numerous, apparently arranged in a dense ring. Stigmas 9.

FIG. 220.—GLOTTIPHYLLUM PROCLIVE.
Apical part of leaves, natural size, adapted from Salm Dyck. Flowers sessile or sub-sessile.

branous at the tips convex (not keeled) on the back. Corolla 2–2 $\frac{1}{2}$ inches in diameter, expanding in the morning in bright sunshine, and lasting 4–5 days, not scented; petals numerous, in about 2 series, 14–15 lines long and 1 line broad, linear, acute, clear yellow, slightly shining, paler on the back. Stamens very numerous, erect in a ring around the stigmas and top of the ovary, about 3 lines long; filaments and anthers orange-yellow. Stigmas 10–11, about 1 line long, radiately spreading, plumose, greenish-yellow. Ovary partly superior, flattish-convex on the top, 10–11-celled; placentas on the floor or outer walls of the cells. Capsule about 8 lines in diameter and 4 lines long or deep, half-superior, about equally flattish-convex above and beneath, with 10–11 valves and cells; structure as for the genus.

Mesembryanthemum longum, Haw., *Obs.*, p. 177 (1795). *Misc. Nat.*, p. 34 (but not of *Syn. Pl. Succ.*, p. 221, and *Rev. Pl. Succ.*, p. 96); N. E. Br. in *Journ. Linn. Soc., Bot.*, Vol. XLV, p. 70. *M. linguiforme* var. *d.*, Linn. *Sp. Pl.*, ed. 1, p. 488, founded upon *M. folio linguiformi longiore*, Dillen. *Hort. Elth.*, p. 238, t. 185, f. 227. *M. linguiforme*, D.C. *Pl. Grass.*, t. 71. *M. linguiforme* vars. *longum* and *pustulatum*, Berger, *Mes. und Port.*, p. 240. *M. pustulatum*, Haw., *Suppl. Pl. Succ.*, p. 88

FIG. 218.—GLOTTIPHYLLUM TAURINUM.
Sketch of growth, reduced, and apical part of leaves, natural size, adapted from Salm Dyck. Flowers sessile.

which is a synonym of 13, *G. taurinum*, N. E. Br.; and var. *heterophyllum*, which is a synonym of 16, *G. longum* var. *hamatum* N. E. Br.

13. G. taurinum, N. E. Br. in *The Gardeners' Chronicle*, 1922, Vol. LXXI, p. 9 (Fig. 218).—Leaf-pairs "obliquely cruciate" or obliquely crossing one another, 2–2 $\frac{1}{2}$ inches long and 6–9 lines broad, semi-terete, flat above, obliquely convex on the back, one leaf often oblique (compressed and keeled) at the obtuse apex, very thick, upcurved or incurved, often somewhat finger-shaped and nearly as large as a finger, "the younger always incurved and resembling the horns of a bull," yellowish-green (in summer time), somewhat pellucid-punctate. Flower sessile. Calyx bifid, with the lobes unequally membranous and keeled, according to Haworth, but the flower he examined was doubtless abnormal and normally it probably would be 4-lobed. Stigmas 8–9, plumose. Corolla not described by Haworth, but according to Salm Dyck's figure, quoted below, it is about 2–2 $\frac{1}{2}$ inches in diameter, with the petals in

(1819), and *Rev. Pl. Succ.*, p. 96; Salm Dyck, *Mes.*, §8, f. 10, and var. *lividum* Salm Dyck, §8, f. 10b; N. E. Br. in *Journ. Linn. Soc. Bot.*, Vol. XLV, p. 133. *G. pustulatum*, N. E. Br., in *The Gardeners' Chronicle*, 1921, Vol. LXX, p. 327.

Port Elizabeth Division: near Port Elizabeth, Burchell, Uitenhage Division: common about Zwartkops, Despatch and Perseverance, Muir 3823! and near Uitenhage, 17-170 feet above sea level and flowering in December and January, Muir 3824! Introduced into cultivation about 1700 or earlier, as the bad figure in Volekammer, *Flora Noribergensis*, p. 165 is doubtless intended to represent this species.

In my previous account of this genus in *The Gardeners' Chronicle*, as above quoted, I was not sure of the correct identity of *G. pustulatum*, because I had not then seen any specimen definitely known to come from the region of Port Elizabeth Division, where Burchell found it. But now that Dr. Muir has sent me plants from that area which are unquestionably *G. pustulatum*, I find that (as might be expected from its being a native of that well explored region) it is not uncommon in cultivation, and that beyond doubt is the same as *G. longum*,

longiore of Dillenius, this may be it, but if so he has delineated the leaves too long." Later, (*Rev. Pl. Succ.*, p. 96) he states that *M. adscendens* is "probably a variety of *M. longum*." This seems to indicate that he was not very clear as to what *M. longum* was. All the above are described as having the pedicel "longer than the calyx" or "two inches long or more." But under *M. longum* in his *Rev. Pl. Succ.*, p. 96, he describes the flowers as subsessile! So that this would appear to be some different species. Evidently there is some confusion, for under *M. longum* var. *flaccidum* on p. 96 of *Rev. Pl. Succ.*, Haworth quotes both Volekammer's figure mentioned above and the figure in the *Botanical Magazine*, t. 1866, as representing the same species. But Volekammer's plant has erect or ascending long leaves and pedicellate flowers and is no doubt a bad figure of *G. longum*, while *Bot. Mag.*, t. 1866, represents a plant with short leaves pressed down close to the ground and sessile flowers and belongs to *G. depressum*.

Var. hamatum, N. E. Br. (Fig. 222).—Growth pressed upon the ground. Leaves not spreading but directed forwards in the direction of growth, 2-3½ inches long, 7-10 lines broad and one leaf of a pair 3-4 lines thick and the other 4-5 lines thick, strap-shaped, straight or slightly upcurved edgewise, the smaller leaf flat or faintly convex on the face, convex on the back and obtuse at the apex, and the larger leaf of each pair with the face somewhat obliquely concave, from being raised all along the lower margin into a strong and somewhat acute ridge, obliquely and bluntly keeled on the back, and with a very large and conspicuous obliquely incurved hook at the apex; both leaves have a pustule or swelling at the base; surface smooth and shining, and the surface-cells neither raised nor depressed as seen with a strong lens, light green. Pedicels 3-7 lines long, slightly compressed and slightly 2-edged, 3-3½ lines broad. Calyx (a dried flower only seen) subequally 4-lobed; lobes about 4-5 lines long and 3½ lines broad, ovate, two of them acutely keeled. Corolla about 2¼ inches in diameter according to the figure; petals numerous, in 2 series, free or nearly so, apparently 10-12 lines long and ¾ line broad, cuneately linear, obtuse, yellow. Stamens very numerous, about 3 lines long, yellow. Stigmas 8-9, about 1 line long, spreading, plumose. Capsule when closed 7-8 lines and when expanded 12-15 lines in diameter, shortly and broadly obconic, flattish, with 8-9 gaping ridges on the top, and with 8-9 valves and cells; brown outside, pallid within; valves reflexed; expanding keels distant, subparallel, with acute and microscopically denticulate edges, pale ochreous-brown or honey-coloured, tipped with a linear or oblong-linear membrane; cells acutely roofed and the opening nearly closed by a very large white tubercle. Seeds ½ line in diameter, compressed-globose, with a small inflexed nipple, smooth, pale brown.

Mesembryanthemum heterophyllum, Jackson, in Andrews, *Bot. Rep.*, Vol. VIII, t. 540 (1808), not of Haworth nor Salm Dyck. *M. angustum* var. *heterophyllum*, Haw., *Rev. Pl. Succ.*, p. 102.

Uitenhage Division: Near Uitenhage, 170 feet above sea level, Muir 3,824 growing on the same root as the type form! ex Dr. Muir.

When I received a plant of this remarkable form from Dr. Muir, I at once recognised it as being the same as that figured in Andrews' *Botanical Repository* as above quoted, of which I cannot find any record that it has been in cultivation here since the period of that figure. As I received it without information of its origin I naturally considered such a distinct-looking plant to be a distinct species, and made the above description of it. When, however, I received information of its origin from Dr. Muir, it was as follows:—"My *Glott. pustulatum* and your proposed *Glott. hamatum* both grew on the same root, and are both 3,824 from near Uitenhage, 170 feet. You get flat adult leaves and leaves extensively hamated as you noted. The latter is one of the turgid very succulent forms which it assumes. Some of them are as hooked as the hooked index finger. My 3,824 I collected myself. I have other collections of the same plant which I brought

from gardens at East London. They were also collected in Uitenhage Division at Dispatch, and taken to East London, and they show the same heterophylly." If collectors had only sent such valuable information as this with plants sent to Europe many errors would have been avoided; for I doubt if any cultivator or botanist in this part of the world without knowledge of the fact would have suspected that the two forms of leaves represented by Figs. 221 and 222 grew upon the same root and are therefore not even legitimate varieties, although, for garden purposes, I have here so considered them. It is remarkable that besides the difference in the shape of the leaves, the portion of the plant sent to me with hooked leaves also differs from the typical form of *G. pustulatum* by having shorter pedicels and fewer stigmas and valves and cells to the capsule.

The only other known species described as having a pustule at the base, are the allied *G. erectum* (which differs by its ascending stems and leaves, and by its leaves being more acute and more centrally pointed), and the very dissimilar *G. grandiflorum* and *G. Salmii*, which both have sessile flowers.

FIG. 222.—GLOTTIPHYLLUM LONGUM VAR. HAMATUM.

Growth with three pairs of leaves, reduced, to show pose; and the apex and base of other leaves, showing hook and pustule, natural size. Flowers pedicellate.

I am informed by Dr. Muir, to whom I am indebted for living native material of this species and its varieties, that "in its native habitat a number of the growths grow from one stem, and as they get larger tend to slope towards the ground. They form patches a yard or more in diameter, so dense that the ground is completely covered. The leaves are pale green, and when they get water reach a length of ten inches." Figs. 221 and 222 are both made from the plants sent to me by Dr. Muir under No. 3,824 as being portions from the same root, as above stated. The plant from Alice, which I formerly thought might be *G. pustulatum*, proves (now that I have seen the true *G. pustulatum* (i.e., *G. longum*) from its type locality) to be distinct, and belongs to the next species, *G. erectum*.

M. longum vars. *angustius*, and *purpurascens*, Haw., *Rev. Pl. Succ.*, p. 96-97; Berger, *Mes. und Port.*, p. 240 are quite unknown, and may possibly belong to some other species. N. E. Brown.

(To be continued).

FIG. 221.—GLOTTIPHYLLUM LONGUM.

Apical part of three leaves, and base of a leaf with pustule, all from one plant; natural size. Flowers pedicellate.

although neither Dillenius, De Candolle nor Haworth mention or figure the pustule at the base of the leaves, but as it is often not very conspicuous unless sought for, and not so distinct in this country as on native-grown specimens, may easily have been overlooked by them, or considered to be of no specific significance at the period (1795) when Haworth first described the species, for the pustule was not noted as a character of any species of this genus until twenty-four years later, when *G. pustulatum* was first described. Dillenius and De Candolle represent the pedicels as being 2½-3 inches long, but this, in my experience, is unusual, and must be due to some condition of cultivation.

It is somewhat remarkable that Haworth seems uncertain of his identification of *M. longum*, and must certainly have had two different species under that name. For in 1795, under his original description, he states that:—"Mr. Aiton does not notice this plant in his *Hortus Kewensis*, but I have seen it very fine at Kew." And in his *Synopsis Plantarum Succulentarum* (1812), under *M. adscendens*, he writes: "If the next species but three (i.e., *M. longum*) is not the *M. folio linguiformi*

IMPROVING THE FLAVOUR OF APPLES AND PEARS.

THAT there is a remarkable difference in the quality of many varieties of Apples and Pears grown under differing conditions is well known. The reason for such differences is not altogether understood, but soil is generally recognised as having considerable effect.

It does not always follow, but it is often the case, that when fruits are grown under conditions which favour the production of exceptional size a certain amount of coarseness in the flavour is noticeable. Certain types of stocks appear to favour such coarseness to some extent, while other types tend to counteract it. Dwarfing stocks tend to refine the flavour of the fruits.

Lack of flavour often occurs where rank manure has been applied freely to the soil, especially where young trees are concerned. Manuring is undoubtedly beneficial, but manure which has stood for some time in the heap should be used for the purpose. A further cause of inferior fruit may be found in the use of fertilisers of an unsuitable nature, while the use of suitable fertilisers may tend to improve the flavour very markedly.

So far as the influence of soil is concerned, it is usually found that fruits of fine quality are produced from trees grown in soil containing a proportion of gravel, though such soil does not always encourage the heaviest of crops. Soils containing lime or chalk produce fruits of excellent quality.

Every effort should be made to improve soils on which fruit of poor quality is produced, and though this is a difficult task it is quite possible to succeed. Drainage is the first matter needing attention. Soil on which fruits are grown should always be thoroughly drained. A dressing of lime well worked in around the bases of the trees will have a refining influence upon the quality of most fruits, and it is difficult to imagine poor flavour in either Pears, Apples or Plums grown in well-limed soil.

The soil should be kept in good condition by regularly digging around the bases of the trees. This may not have a direct influence upon the flavour, but it has a tendency to keep the trees in a healthy condition and prevent the rankness of growth which is so often associated with poor flavour.

From soils which produce dessert Pears and Apples far bigger than the average size of the variety, the fruits are often of harsh or inferior flavour. Where this is the case it is often possible to remedy the defect by a dressing of some potash manure, together with ring barking or root pruning the tree at the proper time. These operations, taken together, have a tendency to produce fruit of excellent quality and size, and at the same time the continued productiveness of the trees is ensured.

It will be seen that while it is not possible to control flavour in fruits to quite the same extent that it is possible to deal with colour, the grower can, nevertheless, improve the flavour, where necessary, very markedly. Both in private gardens and commercial plantations, refined flavour is appreciated and the work necessary to produce it is well repaid at harvest time. *J. W. Morton, March.*

FRUIT GARDEN.

BULLACES AND DAMSONS.

BULLACES and Damsons are of considerable value for culinary purposes and for preserving while certain varieties of Damsons form a palatable addition to the dessert. They are particularly hardy, and trees, with advantage, may be planted to form shelters or wind-screens for the fruit plantation.

The Bullace is indigenous to Great Britain, and its fruits may be made into an excellent preserve. Damson cheese, Damson jam and bottled Damsons are of first-rate quality and are valuable additions to the preserve cupboard. In some districts a palatable wine is made from the fruits.

It is usual to cultivate these fruits in standard or half-standard forms, and the removal of

crowded growths represents the necessary pruning.

The Black Bullace is occasionally found in hedges and woods; the small, black fruits, covered with a thin bloom, are of rather austere flavour, but improve under the influence of October frosts.

Shepherd's Bullace is a large, greenish-yellow variety, round to oval in shape; the tree is of upright growth.

Langley Black Bullace, ripening in November, is of medium size, oval, dark purple, of fine flavour and considerable value; this fruit was raised by Messrs. J. Veitch and Sons (Farleigh Damson \times Early Orleans) and introduced in 1902.

Royal Bullace ripens its fruits in early October; they are yellowish-green, faintly mottled with red on the side next the sun. The flavour is brisk, with sufficient sweetness to make it agreeable. The tree is an immense bearer. Essex Bullace and White Bullace are other well-marked varieties.

Of Damsons, The Merryweather is outstanding. The fruits mature late, are large, roundish, and black, with firm flesh. The tree is vigorous. This is a fruit of very considerable value for culinary use and preserving. It was introduced by Messrs. Merryweather and Sons in 1907.

Farleigh is a late Damson; the fruits small, oval, black; it is a self-fertile variety, a great cropper and of compact growth. It was found wild by Mr. Crittenden, of Farleigh, Kent.

Frogmore produces fruits of remarkably sweet flavour, and these mature early; they are roundish-oval, purplish-black, with a thick bloom. Partially self-fertile and a prodigious cropper, this Damson originated in the Royal Gardens, Frogmore, about 1870.

Bradley's King is of medium size, oval, black, with a very thick bloom; when fully ripe, the fruits are of fine flavour. This is a self-fertile variety.

The Prune Damson has been known since the seventeenth century, and is, perhaps, the finest culinary variety. The fruits are small and tapering, of very dark colour, with a thick bloom. Unfortunately, it is not a regular cropper. The tree is of weeping habit.

Other Damsons are the White, Dalrymple and the Common.

The Zwetche produces small, long, oval, fruits, dark blue in colour, and excellent for stewing or bottling. The flesh is firm, juicy, sweet and separates from the stone. This is largely grown on the Continent and is known as German Prune, German Quetsche, Leipzig, Sweet Prune and Turkish Quetsche. *A. E. R.*

APPLES OF PECULIAR COLOUR.

BLUE Pearmain is a useful late Apple of large size, with the skin striped and blotched with dark purplish-red, over a dull ground; it gains a bluish tint from the white bloom it carries. Large russet yellow dots are sprinkled all over the skin, and the bloom which overspreads it makes the fruit very noticeable.

Some thirty years ago I found several trees of Hoary Morning distributed over the county of Suffolk and was always interested in them because of the intense colouring of the fruits. The latter are large, roundish, somewhat flattened and angular; the skin yellowish, marked with broad, pale red stripes on the shaded side, and broad, broken stripes of bright crimson on the side next the sun, while the whole surface is entirely covered with a thick bloom, like the hoar frost. This very attractive Apple has a yellowish-white flesh that is tinged with red just under the skin; the flavour is brisk, juicy, rich and slightly acid.

Hollandbury, one of the most beautiful and showy of Apples has very large, roundish and flattened fruits with irregular and prominent angles extending from the base to the apex. The skin is deep yellow, tinged with green on the shaded side, but bright deep scarlet next the sun. The white flesh is tinted with green, delicate, tender and juicy, with a brisk and pleasant flavour. Hollandbury is an effective Apple on the exhibition table.

Sops-in-Wine is a very ancient English culinary Apple of rich, deep chestnut colour, approaching orange-red, with a yellow shading, minute dots and a covering of delicate white bloom. The flesh is red, as if soaked in wine,

tender, sweet, juicy and of fair flavour. A few old trees of this variety remain in the Herefordshire orchards, but I have never heard of any one renewing the stock. I have a strong growth grafted on a Red Victoria, as I consider Sops-in-Wine is one of the showiest Apples obtainable. *Pomona.*

ALPINE STRAWBERRIES.

BECAUSE of the difficulty experienced in many gardens with the large-fruited varieties, it is probable that more interest will be taken in the cultivation of alpine Strawberries.

The Alpine Strawberry, at its best, is much appreciated as a dessert fruit and is also in demand for bottling. Plants are easily raised from seeds, and an early sowing may be made in January. Sow the seeds in pans filled with a light, rich compost and place them in gentle heat. The seedlings may be pricked out into boxes or on a bed under a frame. Air must be admitted carefully and the plants gradually hardened.

Choose a partially-shaded site for the beds; an east or north border is generally the most convenient. Alpine Strawberries may also be planted under standard Apple or Pear trees. They thrive in a deep, rich, moist soil. Plant them eighteen inches apart each way and never allow them to suffer from drought. Mulching is advisable, and the mulch may consist of leaf-mould or manure from a spent hot-bed. Short, clean straw may be added before the fruit commences to colour.

Fruits from the early-raised plants will ripen during September or earlier (according to the season and locality). The ripe fruits do not suffer from damp so quickly as in the case of the large-fruited varieties.

Stock may also be raised from seeds sown in drills on a bed of light soil in the open, during the spring or autumn. Draw the drills nine inches apart and transplant the seedlings before they become crowded. Such plants will produce an early crop the second year, and continue in a fruiting condition for several months, under liberal treatment.

Fortunately, birds do not pay much attention to the fruits of the Alpine Strawberry.

There are several good varieties, one of the best being Rouge Amelioré (syn. Improved Red) which is very prolific and hardy. The fruits are long and much larger than those of the ordinary Alpine Strawberry. The variety Blanc, with white fruits, is distinct and useful. *Colin Ruse.*

FRUIT REGISTER.

APPLE DUCHESS'S FAVOURITE.

THIS brightly-coloured Apple is also known as Duchess of Gloucester and Scarlet Incomparable; the fruits are of small to medium size, somewhat round or bluntly angular, the colour a most brilliant red, except when the fruit is shaded, and then it is yellow. The yellowish flesh is tender, juicy and well-flavoured, but sometimes it is suffused or stained with red, strongly reminiscent of the variety Sops-in-Wine.

A prolific cropper, this Apple succeeds in any form and is, I believe, frequent in the orchards of south-eastern counties. Duchess's Favourite was raised at Addlestone by a nurseryman; the Duchess of York of that period having expressed appreciation of the fruit's flavour suggested the name by which it has since been known.

APPLE ADAMS'S PEARMAIN.

NOR a single writer of note has ever given us the origin of this excellent late dessert Apple. Mr. A. Partridge, late of Wharton Court, near Leominster, stated that his grandfather, named Adams, claimed to be the raiser. He raised a number of seedlings from the refuse of the cider mill and selected this particular variety for planting in the garden. Another story is that Adams's Pearmain was known in Norfolk under the name of Norfolk Pippin.

The fruits are of medium to large size and of beautiful colour; the flesh is yellowish, crisp, juicy, rich and sugary, with a perfumed flavour. The Apple is in season during February. The tree is a free cropper and a very healthy grower. *Pomona.*

VEGETABLE GARDEN.

STORING ONIONS.

VARIOUS methods are adopted for storing Onions, and the article in the issue of *The Gardeners' Chronicle* for November 12, on the Dutch method, is very interesting. It appears that the climatic conditions in Holland very much resemble those which prevail around the cotton districts of Lancashire in being very moist. These particular moist areas I find do not allow the Onions to ripen off in the ground so early or so well as in more favoured districts, therefore one has to resort to some other method of ripening the bulbs for keeping purposes.

Having to keep up a constant supply for a very large hospital until April (when the average English Onion begins to grow out), I have adopted the method illustrated in Fig. 222.

I may mention that 22° of frost is the most I have experienced, with no ill effects, but the Onions must not be handled until the frost has thawed out of them.

I partially lift the whole crop, some 20,000, at the beginning of September. The Onions

watered a few hours before cutting takes place. So soon as each cut is made the wound should be held for a few seconds in boiling water, and if any leaves are to be removed, boiling water should also be used to seal the wounds thus made. Under this treatment Poinsettias will last splendidly for a fortnight to three weeks. After fourteen days the leaves will lose their colour, but the bracts will remain almost perfect. *A. Lyddiatt, Heytesbury House Gardens, Wilts.*

Pernettya mucronata.—The seedling forms of this evergreen shrub are very effective when planted in bold, irregular groups in the woodland garden. The small, white, bell-shaped flowers open in May and are in pretty contrast with the new, bright-red shoots and small, deep-green, prickly leaves. Berries are freely produced in the autumn and often remain through the winter, their colours ranging from white and pale pink to crimson and purple. A curious fact I have noted this year is that two large bushes are flowering for the second time but are bearing no fruits. Seedlings vary in habit; there are dwarf, prostrate, erect and drooping varieties; the erect sorts often grow from two to

FIG. 222.—A METHOD OF STORING ONIONS DURING WINTER.

are planted out, as the method of sowing outside is very unsatisfactory in this district. At the end of September, when the tops are still green, they are tied in bunches of six or eight, two bunches being tied together and slung over rows of nails on the side of an outbuilding, preferably the gable ends. The green tops make a kind of thatch as the work proceeds from the bottom upwards. No further attention is necessary until the Onions are required for use. In this way the sun and wind gradually ripen the bulbs, and they become equally as firm as those grown and stored under more ideal conditions. I am invariably asked if the frost spoils them, presumably because many writers recommend storing under cover. I have practised this method for the past six years and can thoroughly recommend it. *A. Falconer, Cheadle Royal Hospital, Cheshire.*

HOME CORRESPONDENCE.

Poinsettias.—*Euphorbia pulcherrima* is a most useful plant for Christmas decorations. It is not frequently grown for cutting, but is nevertheless suitable for that purpose. Plants may easily be obtained grown to a height of five feet to six feet, with heads of brilliant scarlet bracts twelve to fourteen inches in diameter. It is surprising how few decorators know how long the Poinsettia will last in the cut state, in water. I find it most beneficial to place a tablespoonful of table salt to each gallon of water used for the vases in which they are placed. It is essential to seal the ends immediately the stems are cut to prevent the rapid discharge of the milky juice with which the Poinsettia is so plentifully supplied, but it must be remembered that plants should be well-

three feet in height. Pernettyas succeed best on heavy soils of a peaty nature, either in full sunshine or half shade. *S. Bowler.*

Pea Amateurs' Pride.—As the season is drawing near when seed lists are perused, I venture a few words in praise of Pea Sutton's Amateurs' Pride. It is a first-rate variety recommended to me by a keen vegetable grower. I gave it a trial, and found it very useful. Choosing an open site in the kitchen garden I opened a trench two feet wide by two feet six inches in depth, forked into the bottom plenty of well-decayed manure, turned the first spit on to this, gave a good dressing of superphosphate, and finally filled the trench to the ground level. Nothing further was done until sowing time. Amateurs' Pride is a variety of excellent flavour, the pods containing nine to eleven Peas; it grows from five to six feet tall, and is a variety I can thoroughly recommend. *James Findlay, Ash Grove Gardens, Sevenoaks.*

Birds and Fruits.—I venture to ask your correspondents who are so loud in their praises of the vast amount of good done by the blue tits, what means they adopt to protect Doyenné du Comice Pears and Cox's Orange Pippin Apples? If they do not grow these fruits they are hardly in a position to know anything of the trouble caused. I quite agree with Mr. C. Nicholson when he states that the vast amount of good the birds do at other times is unknown. If he had spent as many seven-days-a-week in trying to protect fruits from the ravages of birds as I have done, he would understand an Englishman's desire to go out and kill something. Practical gardeners will appreciate Mr. H. E. Durham's interesting notes on the subject. *J. Kneller, Penrhyn Castle Gardens.*

SOCIETIES.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

At the meeting held on Friday, November 25, the members of Committee present were:—Messrs. A. Keeling (in the chair), R. Ashworth, D. A. Cowan, A. Coningsby, J. Evans, G. V. Llewelyn, D. McLeod, W. J. Morgan and H. Arthur (Secretary). Mr. J. Thrower was invited to sit with the Committee.

FIRST CLASS CERTIFICATES.

Cypripedium Montcalm var. *Hy. Astley Bell*.—A large, shapely flower with a round dorsal sepal three-and-a-half inches across, heavily spotted, with a broad, white margin; petals broad and lip dark bronze.

Odontoglossum Matador var. *Grand Duke Nicholas*.—A large flower of good form; solid chocolate-red, with white margin. Both from Mr. JOHN EVANS.

Brasso-Laelio-Cattleya Muriel, *Llewelyn's* var. —A large, symmetrical flower, seven inches across, of even colour; the lip has a yellow throat. From G. V. LLEWELYN, Esq.

AWARDS OF MERIT.

Cattleya Suavior, *Llewelyn's* var.; *Brasso-Cattleya Rosita*, *Llewelyn's* var.; and *Laelio-Cattleya Carmencita* var. *Hesketh*.—From G. V. LLEWELYN, Esq.

Laelio-Cattleya Sunbelle (L.-C. *Serbia* × *C. Thora*).—A very promising seedling. From Messrs. J. AND A. McBEAN.

CULTURAL CERTIFICATES.

To Mr. JOHN EVANS, for *Cypripedium insigne* *Sanderæ* and *C. Corneyanum*.

GROUPS.

G. V. LLEWELYN, Esq., Southport, showed a group to which a Silver-Gilt Medal was awarded; this contained *Cypripedium Our King*, *C. mirabilis*, *C. Boltonii*, *C. Colin*, *C. Dreadnought*, *C. Mulatto*, *C. Leonidas*, *C. Actæus revoluta*, and *C. Earl of Tankerville*; *Brasso-Cattleya Maroniae* and *B.-C. Jupiter*; *Laelio-Cattleya Schröderæ*; *Odontoglossum Woodroffiae*, and others.

Mr. JOHN EVANS, Colwyn Bay, was also awarded a Silver-Gilt Medal for a group that contained *Cypripedium Montcalm*, *C. insigne Sanderæ* (thirteen flowers); *C. Corneyanum* (eleven flowers), *C. Martins*, *C. Gwen Manners*, *C. Lady Dillon*, *C. Silene*, *Odontoglossum Matador*, *Odontioda Bradshawiae*, *Calanthe Harrissii*, *Vanda coerulea* and *Oncidium incurvum*.

Captain W. HORRIDGE, Bury (gr. Mr. A. Coningsby) sent *Odontoglossum Senlac*, *Coelogyne barbata* and *Cypripedium insigne* *Rossendale*. Messrs. J. AND A. McBEAN, Cooksbridge, exhibited *Laelio-Cattleya Sunbelle*, *Odontoglossum St. Elmo* and *O. Portheus*. Mr. D. McLEOD, Chorlton-cum-Hardy, showed *Cypripediums* in variety.

THE ORCHID CLUB.

At the exhibition meeting held on December 2, there was a very extensive and brilliant display of select Orchids, *Cypripediums*, *Odontoglossums* and species being the predominant features.

PREMIER DIPLOMAS.

Cypripedium Memoria J. H. Walker, var. *Mars*.—A medium-sized flower of excellent shape and proportions and brilliant colour. The flat, orbicular dorsal sepal, three-and-a-quarter inches across, is of a uniform bright crimson colour with a white tip. The well displayed petals are yellow, stained with mahogany-red, and the lip is of similar colour.

Cypripedium Melody (C. *Perseus*, var. *Ruth* × *C. Charlotte Dillon*).—A perfectly-shaped flower of unusually beautiful colour. The flat, orbicular dorsal sepal, three-and-a-half inches across, is porcelain white, with a small emerald-green luna, the central and basal parts being marked with crimson spots set in vertical

rows, laterally the spots expand and merge into a continuous zone of brilliant rose colour which is invested by a white marginal band. The horizontal petals, set well up, are Indian-red with a yellow margin, the lip being of like colour.

Cypripedium Morea (*Chrysostom* × *Memoria F. M. Ogilvie*).—A very large flower of perfect shape and proportions, conforming with the best types of *C. Chrysostom*, the colour on the dorsal sepal being clearer and more decided, and the petals broader and flatter.

Cypripedium Makeda (*Lady Dillon* × *Charlotte Dillon*).—A flower of pleasing form and colour; the flat, oval dorsal sepal is white marked with vertical rows of dark crimson spots, leaving a clear white margin. The petals and lip, well displayed, are mahogany-red with a yellow margin.

These new seedlings, flowering for the first time, were shown by the raiser, Dr. CRAVEN MOORE.

DIPLOMAS OF MERIT.

Cypripedium Morcar (*Nesta II* × *C. Hera*).—A large flower of excellent shape, the flat, orbicular dorsal sepal, three-and-three-quarter-inches across, is white, marked in the central part with a few dark crimson spots surrounded by a zone of crimson speckling, leaving a broad, white marginal band. The petals (rather small for the large dorsal) and the lip are green, with brown lines.

Cypripedium Perseus var. *aurantiacum*.—A new seedling closely resembling in general form the F.C.C. variety of this hybrid, but quite distinct in the pleasing orange-brown colouring. Both shown by Dr. CRAVEN MOORE.

GROUPS.

Sir WILLIAM THOM (gr. Mr. Williams), exhibited a selection of interesting and meritorious *Cypripediums*, including *C. Prince Albert*, *C. Cappa-Magna*, *C. Monialis*, *C. Mullato splendens*, *C. Undaunted*, *C. Merlin* and a few new seedlings of considerable promise, together with several plants of *Oncidium varicosum* and *O. Forbesii*.

Mrs. HARDY showed a small group of high-class *Odontoglossums*, all with full spikes, including a beautiful variety of *O. Princess Yolando*, with large, well-shaped flowers of royal-purple colour; a fine white hybrid *crispum*, and excellent varieties of *O. crispum xanthotes*.

Mrs. STOCKWELL (gr. Mr. Weaver), exhibited a group of well-grown *Cypripediums*, including *C. Ballet Girl* with three and four flowers, *C. Cyril Lee*, *C. Hermes* and several others.

A. T. CUSSENS, Esq. (gr. Mr. Dalglish), had a beautifully-arranged group of *Cypripediums* and *Cymbidiums*, relieved by Ferns and small Palms. Among the *Cymbidiums* an especially fine form of *C. Doris magnificum* was conspicuous, and among the *Cypripediums* there were some fine flowers of *C. Maudiae magnificum*, *C. King George V*, *C. Memoria F. M. Ogilvie* var. *The Premier*, *C. Nandii*, a delicate lady-like flower, and some first-rate *C. Niobe* hybrids.

B. J. BECKTON, Esq. (gr. Mr. Stewart), exhibited an extensive and interesting selection of species, together with a few good *Cypripediums*, viz., *C. Warrior*, *Green's* var., *C. Swallow*, *Westonbirt* var., and *C. John Hartley*; and among the species were beautiful plants of the curious *Bulbophyllum lemniscatum*, the brilliant yellow, aromatic *Lycaste cruenta*, the pretty little *Odontoglossum Kramerii alba*, and the sweetly-scented *Trichosma suavis*, while *Coeloglyne barbata*, the elegant *Cyperorchis Mastersii alba* and the bizarre *Mormodes Wendlandii* were also noteworthy.

Dr. CRAVEN MOORE (gr. Mr. Gilden) exhibited a group of *Cypripediums* of unusual merit; it included large plants of the finest *Westonbirt* varieties, and a range of new seedling hybrids in which form and beautiful colour had been attained in a degree not previously seen. F. T. PAUL, Esq., showed a selection of *Cypripediums* in which a beautiful variety of *C. Fairrieanum*, a fine form of *C. Perseus*, and a beautiful plant of *C. Pixie* were conspicuous. W. MORTON JACKSON, Esq., exhibited a finely-flowered plant of *Eria rhyncostyloides*.

BUCAREST FLOWER SHOW.

THE Bucarest (Roumania) Fruit and Flower Show, which has now been established five years, continues to be an unqualified success. The weather was a great help, on November 5, as at the opening of the show the temperature stood at 20° Reaumer, and kept so during the five days of the exhibition; the fine weather brought out a crowd of visitors who helped to swell the fund for the much needed new pavilion.

The exhibition was opened by the Ex-Queen of Greece, accompanied by Dr. Argentoianu, Minister of Agriculture, the Minister of Justice, the Bishop of Roumania and the Regent. Princess Bibesco and Brigadier-General Lord Thomson, who were staying at Mogosoca during a visit to Roumania, were present and greatly admired the show. Lord Thomson is no stranger here, having been British Military Attaché for Roumania before the war. The President, M. Charles Farando, who hurried back from France, where he had been called as judge in Paris to represent the Roumanian Horticultural Society, gave great credit to the English growers who exhibited there, especially those who showed Carnations.

The President, who made a short speech at the opening ceremony, expressed deep sympathy for the Royal Family in the loss of His Majesty King Ferdinand, and regretted very much that Her Majesty Queen Marie could not be present. The park was in perfect condition and contained a grand display of dwarf Chrysanthemums; in fact, it looked more like spring than November. Great credit is due to the Superintendent of the park, Mr. Z. Bucur, for the way in which his charge is kept.

In the pavilion, where the exhibits were arranged, the display was not quite up to the standard of last year. Vegetables were not so plentiful nor so well arranged. The non-competitive exhibit from the Royal Palace Gardens were not so attractive as last year owing to the Royal Family being in mourning; it consisted chiefly of coloured leaves and branches and wreaths, which were very tastefully arranged at one end by themselves (gr. Mr. F. Rebhunm).

MESSRS. CHARLES FARANDO AND SONS, Bucarest, also exhibited a non-competitive group, of a high standard of merit, at one end of the pavilion; this contained standard Bay trees in tubs, and large vases filled with big blooms of Chrysanthemums, which were very much admired; the varieties included Mr. Phillip Rivoire, Souvenir le Graisivandon, Kara Dow, Captain Foo, Daily Mail and others, with an underground of a bronze Single, dwarf Chrysanthemum.

H.H. PRINCE G. V. BIBESCO, from the Palace of Mogosoca (gr. Mr. J. W. Funge), again secured the Society's Gold Medal for a splendid collection of Grapes and flowers—the former including Madresfield Court, Alicante and Marchal Gallien—dishes of Apples, and Quinces weighing over 2 lb. each, intermixed with plants, single Chrysanthemums, Streptocarpuses and a *Laelio-Cattleya*—the first to be shown at this Society's exhibition.

Mr. A. MONTIGNY showed very fine specimen Palms and Ferns in variety, but none of them was named; this firm also showed some very fine fruit trees including Apricots, Pears, Plums and Apples (Gold Medal).

MESSRS. T. H. SCHEIDEGGER AND SONS, Bucarest, who filled one end of the pavilion with mixed decorative plants and Chrysanthemums, also showed a fine collection of over two hundred named varieties of Cacti which proved very interesting to those who understood them. (Gold Medal). Mr. THOMAS KRAUS, Brasov, again showed first-class Cyclamens and Carnations, and was awarded a Gold Medal. MESSRS. KNIPER AND SOARE, Bucarest, exhibited a fine group of Dahlias edged with Roses (Gold Medal).

Mr. A. CLONARD, Bucarest, had a capital arrangement of seeds and implements. (Gold Medal). MESSRS. A. GIRAUD AND Co., a French firm, exhibited bottled and dried fruits. Mr. W. HUGO, gardener, designer and painter, showed some very fine paintings of gardens and flowers.

Basarabia and other parts of Roumania were represented by exhibits and the Horticultural Schools were well to the front with produce, but the young men they turn out, after training, are not a great success.

The show was a great success financially.

SMITHFIELD CLUB.

THROUGHOUT the week, until Friday evening, the chief interest of the agricultural world has been centred on the great show of fat stock at the Agricultural Hall, Islington, where the world's finest display of fat cattle, sheep and pigs has been seen. Farmers are also keen gardeners, so that while it is primarily the beasts stalled and penned on the ground floor of the hall that they first inspect, the vegetable exhibits in the gallery never fail to receive due attention.

It is in the gallery that the principal seedsmen have their stands. To the average gardener such seedsmen as Messrs. Sutton and Sons, Messrs. Carter and Co., Messrs. Webb and Sons, Messrs. Toogood and Sons, Messrs. Harrison and Sons, and Messrs. E. W. King and Co., are known solely for the excellence of their garden seeds. But they all do enormous business with farm seeds, and it is safe to say that equal care is paid to the strains of the various farm roots and Cabbages as with, for instance, Begonias and Antirrhinums, and perhaps even more. For while with both types of seeds the trueness, vigour and yield of the strains are the subject of regular tests, the additional factor of food content is of immense importance in the farm crop. No matter how imposing the towering arrays of Mangels and Turnips, which are seen at Islington, may be, their size, symmetry and, often, fascinating colouring does not impress the agriculturist unless the guaranteed food content proportion is also present.

While these noble piles of gargantuan roots of perfect form and flat-pol Cabbages of table-top proportions are the chief features of the seedsmen's exhibits, the garden is also well catered for. Close to the broad stairway, Messrs. SUTTON AND SONS had their usual splendid display, which they embellished with vases of Cyclamen blooms, exhibition mounds of Brussels Sprouts of the highest quality, many Onions, such as Veitch's Maincrop, Sutton's Globe and Veitch's Intermediate Beet, Autumn Protecting and Christmas White Broccoli, and little Kohl Rabi of succulent appearance which contrast strangely with the huge specimens of the farm type of the same vegetable. Although it is December, and the shops have put on their Christmas dress, MESSRS. SUTTON AND SONS are able to show, alongside Twentieth Century Mushrooms, Cucumbers of such quality that it would be difficult to surpass them at any summer show. The pairs of Pride of the Market Cucumbers were long and perfectly straight, perfectly matched, and their quality was ensured by the presence of the flowers which still remained at the tips of the fruits. The dishes of Winter Beauty Tomato were also of outstanding merit. Potatoes formed an important feature of the exhibit, and there were excellent dishes of many first-rate varieties, including Argyll Favourite, a white, pebble-shaped tuber; Aberdeen, oval, white; The Sutton Flourball, pink, pebble-shaped; Great Scot, Majestic, Red King Edward and The Bishop.

Leeks were of especially good quality amongst the many vegetables shown by Messrs. J. CARTER AND Co., whose Onions were also of considerable excellence. Holborn Model Leek was not only of good length and exceptional girth, but the stems were unusually firm. The chief Onions were Record, Blood Red and a very good strain of the popular Ailsa Craig. This season, many examples of Brussels Sprouts have been too large for the discerning cook—they have almost the appearance of young Cabbages—but the Sprouts staged by Messrs. J. CARTER AND Co. were ideal in appearance. They were of good, medium size, neither too large nor too small, firm and of fresh green appearance. Their Carrots and Parsnips also were of the best exhibition types. As is right and proper, Potatoes were well represented. The principal

varieties were Di-Vernon, and the similar, though distinct in the purple flushing, Catriona, Arran Victor, Majestic, Red King and Field-Marshall.

A number of well-flowered Cyclamen plants drew attention to the stand of Messrs. E. WEBB AND SONS, and from these the visitors' attention was inevitably drawn to the quality of The Conqueror Tomato, the Webb Brussels Sprouts, Reliance Onion, and such excellent Potatos as King Edward, Katie Glover, Red King and Majestic. In their extensive exhibit, Messrs. TOOGOOD AND SONS set up good mounds of Southampton Champion Onion, Crimson Globe and Southampton Black Beet, their new Scarlet Carrots and many dishes of excellent Potatos.

Beet, of splendid appearance, were shown by Messrs. E. W. KING AND Co., whose chief varieties were Intermediate, of almost perfect oval shape, and Dark Red. Their roots of Snowball Turnip were also of great excellence, while the Scarlet Model, Scarlet Intermediate and Early Market Carrots would also have taken high positions in any competitive show. Other noteworthy vegetables included the Prize-winner Leeks and Arran A.1 Potatos. At one end of this extensive exhibit there was a row of very good exhibition Japanese Chrysanthemums. A particularly good variety of Leek, named Leicester Hero, was shown by Messrs. HARRISON AND SONS, and their Brussels Sprouts fully justified the title of "XXXX." Exhibition Onions, Red Globe and Marble Top Turnips and Early Wonder Beet were also of great merit. Reading Matchless Onions, Scarlet Model Carrots, White Model Turnips, Intermediate Beets and a good selection of Potatos were attractively shown by Messrs. JOHN K. KING AND SONS, while Messrs. ALEX. BLATCHFORD, LTD., staged good specimens of Celery, Globe Beet, Onions, and particularly good Princess Mary Cabbages.

As usual, there were many exhibitors of Potatos, who set up many admirable dishes, both of ware tubers and seed-size of all the best varieties. The largest exhibit, solely of Potatos, was arranged by Messrs. FIDLER AND SON, who included such well-known varieties as Majestic, Red King, Eclipse, Factor, Field-Marshall and Rob Roy. Other exhibitors of Potatos included Messrs. S. THOMPSON AND SONS, LTD., Messrs. W. A. GRAHAM, LTD., Messrs. LITTLE AND BALLANTYNE, Mr. JAMES GRAY, Mr. FRANK K. SHARP, Messrs. ISAAC POAD AND SONS, Mr. HERBERT J. SPEED, Messrs. ROBERT MORRIS AND SON, Messrs. GEORGE WHITE, LTD., Mr. JAMES GARDINER, Messrs. KENT AND BRYDON, Mr. W. J. REID, Mr. R. W. GREEN, Mr. WM. ROBERTSON, Mr. THOMAS McCURE, Mr. JOHN A. GRANT, Messrs. WM. DENNIS AND SONS, LTD., Mr. W. J. CAMPBELL, Mr. A. FINDLAY, Mr. GEORGE SHARP and Messrs. PATTULO, HIGGS AND Co.

Fruit-growers generally do not seem to attach much importance to the opportunities of the Smithfield Club Show, for this year there were only the two customary exhibitors. Messrs. WM. SEABROOK AND SONS had a goodly collection of Apples, and a few specimen trees of various fruits. The Apples included handsome fruits of Bismarck, Ellison's Orange, Cox's Orange Pippin, Monarch, Rival and Rev. W. Wilks. Mr. T. A. SCARLETT brought plants of Edina Black Currant, a very vigorous and fruitful variety which is said to be immune from attacks of the Big Bud Mite. He also had sturdy, well-cropped plants of Brussels Sprouts, Leeks and Potatos.

Meadow Grasses and farm cereals were shown attractively by various firms, particularly Messrs. GARTONS, LTD., and the well-known Vermorel Sprayer was shown, both of knapsack size and on wheels.

READING AND DISTRICT GARDENERS'.

THE interchange of lecturers with the Bristol Society which was an annual event previous to 1914 was happily renewed on Monday evening last in the Abbey Hall, when Mr. R. L. Rogers, landscape gardener, of Redland, Bristol, gave a most interesting lecture on "Colour Planning in the Garden." He drew attention to the fact that to obtain the most pleasing results during the four seasons of the year, whether in small or large gardens, required much thought and fore-

sight, and perhaps more than was generally given to the subject. He gave most useful and practical hints on selecting colour schemes for alpine gardens, herbaceous borders and beds, and named plants, bulbs, flowering trees and shrubs for each section. He also dealt with blue, white and golden gardens.

Several members offered their congratulations to Mr. Rogers for the charming manner in which he had dealt with his subject.

In the competition for three dishes of Potatos, distinct, there were seven entries, and some excellent tubers were shown. The first prize was awarded to Mr. A. W. GOWER, The Gardens, Calcot Grange; the second to Mr. F. HAINES, The Gardens, Calcot Hanger; and the third to Mr. A. H. DOW, The Gardens, Calcot Park.

In the non-competitive section, Mr. C. S. CLACY, The Gardens, Sidmouth Grange, Earley, staged a vase of Chrysanthemum blooms; Mr. A. PARKER, Hazelmere, Reading, showed a collection of Apples, and Mr. J. TAYLOR, Highgrove Street, Reading, exhibited Potatos.

NATIONAL CHRYSANTHEMUM.

ABOUT a dozen new varieties of Chrysanthemums were exhibited before the Floral Committee of this Society on November 28, and the following awards were made:—

FIRST CLASS CERTIFICATES.

Gaiety. V.2.a.—A large Single variety of vivid, velvety, chestnut-crimson colouring, with a golden zone around the centre. Shown by Mr. H. SHOESMITH, junr.

Mrs. E. Page. V. 2.a.—A showy Single variety in which the golden colouring shades from the centre outwards, gradually mingling with the bright chestnut hue of the outer halves of the florets. Shown by Mr. H. WOOLMAN.

John Hall. II. 1.a.—A big exhibition, Japanese variety of light purple colour, some of the flowers showing a mauvy-purple shade on the reverse of the florets. Shown by Mr. G. CARPENTER, West Hall Gardens, Byfleet.

Tom Abbott. II. 1.a.—A large, deep, exhibition Japanese variety with an abundance of bluntly-pointed, canary-yellow florets, the reverse colour being slightly paler. A fine flower. Shown by Mr. H. J. JONES.

GERMAN HORTICULTURAL.

DURING the period from the 5th to the 9th of November, a large Chrysanthemum and fruit exhibition was held by the German Horticultural Society in the Berlin Town Hall. There were, besides those named, a few other exhibits, but these were in a decided minority. Many firms exhibited Chrysanthemums, including OTTO BEYRODT, HERMANN ROTHE, EMIL PRETZEL, RICHARD FREIDRICH, of Berlin-Biesdorf, HEINRICH KRUGER of Charlottenburg, and SPIELBERG AND DE COENE of Berlin-Buchholz. Among the blooms most admired were many of English raising, such as Mrs. R. C. Pulling and Queen Mary; indeed, the nurserymen seemed to have a majority of French and English varieties.

A private exhibitor, FRAU GERTRUDE JEIDELS, of Wannsee, Berlin, showed a variety named Hedwig Heyneck, but Chrysanthemums are evidently not a German speciality. SPIELBERG AND DE COENE had a very fine exhibit of hot-house Grapes, including Alicante, Mrs. Pince, Gros Colman, and Barbarossa. The Grapes were of excellent quality. GEORG MARQUARDT, of Zossen, showed Cyclamens, and close to this exhibit was one of cut Roses from A. BRANDT, of Mahlsdorf.

An interesting exhibit of Chrysanthemums was that from the State Experiment Station at Pillnitz. All the newest varieties were here collected, and they provided a revelation of the beauty and decorative value of the Chrysanthemum at its best.

The celebrated Dahlia raiser, KURT ENGELHARDT, of Dresden, had brought a number of novelties, including one destined for commerce in 1928 named Symbol. A large vase was filled with this variety, which has long, firm stems and pink flowers, fading into white in the centre.

Obituary.

Hermann Stapel.—We regret to learn of the death, on November 8, of Hermann Stapel, who was for thirty-one years Superintendent of the Parks and Gardens Department at Darmstadt. Born of well-to-do parents, Stapel was educated in Jena and afterwards at Weimar, but his love of Nature led him to adopt gardening as his profession, and he went to serve an apprenticeship in the Georgengarten in Hanover, at the same time attending the technical high school, where he obtained a degree in botany and geodesy. After a short period at Charlottenhof-Potsdam, he assisted the landscape gardener, Walter, in laying out new gardens for the Empress Frederick at Schloss Friedrichsdorf, near Cronberg, and was later sent by the Empress to the Royal Gardens at Frogmore, Windsor, for a course of study in English methods of gardening and fruit-growing. On his return to Germany, after a short further stay at Friedrichsdorf, Stapel entered the Parks Department in Berlin, later taking over the direction of the parks and cemeteries at Kottbus where he remained until 1896. In that year he was appointed to his charge at Darmstadt where he found a rich field for his energy and talent in the many large and beautiful open spaces, and in the special labours required on the occasion, for instance, of the Agricultural Exhibition of 1900 and the Horticultural Exhibition of 1925. Among the amenities of Darmstadt under his care may be mentioned the very beautiful Waldfriedhof, where now his ashes will rest. Stapel's was a fine nature, and his many friends will deeply regret the demise of one who knew so well how to combine energy and conscientiousness in work with sympathy and kindness of heart.

ANSWERS TO CORRESPONDENTS.

BIG BUD MITE.—J. L. The best wash for spraying Black Currants that are suffering from attacks of big bud mite is lime-sulphur, used according to directions. The bushes should be sprayed in March or April, according to the season, the best time being just when the buds have burst and the leaves are about the size of a shilling. To make sulphur wash, take two ounces of soft soap and $\frac{1}{2}$ -lb. of flowers of sulphur, and add gradually two gallons of boiling water; mix thoroughly and use when cool. Regarding your vines, if mildew has appeared, sulphur should enter largely into any winter dressing of the rods; it will be found to adhere fairly well if mixed with strong soapy water. Sulphur should also be used in the whitewash for the annual dressing of the vinery walls.

IRON SULPHATE FOR SPRAYING.—A. G. For spraying purposes, sulphate of iron may be prepared by dissolving 25 lb. of the sulphate in one pint of sulphuric acid, and adding fifty gallons of water. This is for winter use only, or for spraying when the buds of vines are in a dormant state; it must not be placed in metal vessels owing to its corrosive action. You may dress your dormant vines with a tar wash made of one part coal tar, and six parts of clay; dry the clay and powder it so that it will pass through a quarter-inch sieve. Mix the tar and clay thoroughly, and add sufficient boiling water to make the mixture of the consistency of paint. Smear the mixture over the dormant rods, but avoid coating the buds themselves, and keep the mixture well-stirred during the process of application. Discretion is necessary in applying such dressings. Safer and equally good results would follow the use of Gishurst Compound; use eight ounces of the compound to one gallon of water, with sufficient clay added to give it the consistency of paint, and fill up all the holes and crevices with pure compound.

MARKETS.

COVENT GARDEN, Tuesday, December 6th, 1927.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Tuesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in the day.—EDS.

REMARKS.—With the exception of Chrysanthemums, which have increased in quantity during the past week, and with disbudded blooms in very little demand towards

the week-end, prices have been slightly on the down grade. Several other lines have been shorter, such as Carnations, Roses, Violets and Gardenias, and for the two first prices were considerably firmer to-day. Arums (Richardias), Lilium longiflorum and L. speciosum rubrum are still in fairly regular supply and remain very moderate in price, considering the unfavourable weather conditions. More Roman Hyacinths have been offered, cut and on bulbs. A few scarlet Tulips were on sale to-day, from Holland. Poinsettias are very limited in quantity, but there is little demand for them at present. Yellow and white Narcissi have been received from home-growers during the past week. White Lilac from Holland is now arriving in better condition.

POT PLANTS.

Business shows considerable improvement in this department. Many plants are now being despatched to the provinces, and large quantities will be forwarded during the next few days; the subjects most in demand are Erica nivalis, E. gracilis and E. hyemalis, in 48's, 60's and thumb pots; Solanums, Azaleas, Begonias, Cyclamens, and Chrysanthemums in 32's, 48's and 60's. Ferns and Palms are also in good demand, and an excellent selection is now on offer in various sizes.

REMARKS.—Business conditions are, perhaps, a shade brisker, but during the past week or so they have been very slow. The Apple trade in particular is bad, for both imported and home-grown fruits. Even at most remunerative prices there is little or no movement. A few English Pears are available and some excellent Californian Doyenné du Comice and Winter Nelis are selling fairly well. Oranges, for the time of year, are cheap and plentiful. Grape Fruits are scarce and prices are a shade firmer. Pineapples are selling moderately well, the latest shipment being a large one. Some Apricots and Peaches from South Africa have arrived this week. Hothouse Grapes have sold rather more freely, but values remain at a steady level. Asparagus from France, Italy, with a little from Devonshire, is selling moderately well. Cucumbers, as is usual at this season, are scarce and costly. A few English Tomatoes arrive each day, but their condition is not generally good, the trade looking to the Canary Islands for their requirements. Arrivals of Mushrooms have not been quite so heavy, but there is no increase in price. The shipment of Madeira Beans this week is comparatively heavy, but there is a good demand for hothouse Beans

and prices are firm. Salads are not selling well, even the best French Lettuce, Endive and Batavia Endive selling cheaply. Green vegetables are a quiet trade, as are Cauliflowers, which are arriving mainly from France, Kent and the west of England. The Potato trade is a little more active, but values remain about the same as previously advised.

GLASGOW.

The cut flower market continued firm last week, when prices of Chrysanthemums were maintained at the former high level. Ada Brooker realised 2s. to 2s. 3d. for 6's; Pink Chieftain, 1s. 6d. to 2s.; Phyllis Cooper, 1s. 9d. to 2s.; White and Yellow Thorpe, 1s. 6d. to 1s. 9d.; Cranford Yellow and Florrie King, 10d. to 1s. 3d.; Jean Pattison and Mary Richardson, 10d. to 1s. 2d.; Almirante, 1s. to 1s. 4d.; Dolores, 9d. to 1s.; Pink Triumph, 6d. to 10d.; Ada Brooker (specials), 6s. to 8s. per dozen; White Beauty (specials), 5s. to 7s.; Framfield Pink, Mary Morris, and Absolute, 3s. to 3s. 6d.; Thorpe, large bunches, 10d. to 1s. 3d.; small, 8d. to 10d.; and Heston White 6d. to 7d. Roses: pink, 6s. to 8s. per dozen; white and red, 2s. to 4s. Carnations, 4s.; Narcissi, 3s. to 4s.; and Lilium longiflorum, 2s. 6d. to 3s. 6d. per bunch.

The fruit market was comparatively quiet for this time of the year, and price movements were narrow and unimportant. The better qualities of Apples were scarce, Canadian Kings, Spies and Greenings being worth 44s. per barrel; Baldwin, No. 1, 36s.; domestic, 30s.; Starks 32s.; York Imperial, 28s. to 32s.; Salome, 28s.; Ben Davis, 25s. to 26s.; Delicious (fancy), 16s. 6d.; Seagrave, 15s.; and Grimes' Golden, 15s. 6d. to 16s. 6d. Recent arrivals of Jonathan were reported to be frosted, and values ranged from 11s. to 15s. per case. Valencia Oranges made 16s. to 28s. per case, according to counts; Jaffas, 14s. to 15s.; Mandarins, 1s. 3d. to 2s. per tray. Grape Fruit, 20s. to 22s. per case; Murcia Oranges, 300's, 17s. to 20s.; 360's, 15s. to 17s.; and 340's, 18s. to 20s. Tripoli Lemons, 250's, 16s.; Palermo, 300's, 20s.; Murcia, 300's and 240's, 24s.; Winter Nelis Pears, 15s. 6d. half-case; Californian, 26s. to 28s.; home-grown Grapes, 3s. 6d. per lb.; Belgian, 1s. 2d. to 1s. 6d.; and Tenerife Tomatoes, 18s. to 30s. per bundle.

In the vegetable department, Cauliflowers sold at 7s. to 9s. per crate; indoor Lettuces, 1s. 9d. to 2s. per dozen; outdoor, 3s. to 3s. 6d.; French Carrots and Turnips, 1s. 2d. per bunch; Mushrooms, 2s. 6d. per lb.; Dwarf Beans, 1s. 6d. to 1s. 8d.; Endive, 4s. per dozen; and Brussels Sprouts, 2s. to 2s. 6d. per stone.

GARDENING APPOINTMENT.

Mr. A. Aylett for the past seven years gardener to H.I.H. PRINCESS NAPOLEON, at Farnborough Hill, Hampshire, and the Chateau de Ronchinne, Lustin Namur, Belgium, as gardener to VISCOUNT FITZALAN OF DERWENT, Cumberland Lodge, Windsor Park, Berkshire. (Thanks for 2/6 for R.G.O.F. Box.—EDS.)

BINDING CASES

for the

GARDENERS' CHRONICLE

Readers of *The Gardeners' Chronicle* are reminded that we supply artistic green, gilt-lettered binding cases which accommodate twenty-six or twenty-seven copies of the paper (i.e., a half-yearly volume). These cases constitute an excellent temporary binding, as the copies are fastened into the case by a simple method which entirely prevents their falling out or becoming loose.

Price of each case 5/6 post free.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the past fifty years at Greenwich, 38.6.

ACTUAL TEMPERATURE—
The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, December 14, 10 a.m. Bar. 29.7. Temp. 38°. Weather, Wet.

The Spraying of Fruit Trees. THE use of carbolineum washes for the winter spraying of fruit trees, which has been practised now for several seasons, has given such excellent results that it may now be regarded as an established practice in orchard management. Needless to say, it is essential that spraying with one or other of these materials should be done during the period when the trees are dormant. Of carbolineum sprays there are many, and no doubt not a few of them are excellent. Carbokrimp is one which has been widely and successfully used. Mortegg is another, which, as judged by the results of trials recently carried out by the Research staff of a private firm,* appears to effect a very thorough control of insect pests. Comparative trials of Carbokrimp (7½ per cent.) and various proprietary carbolineum washes, including Mortegg (7½ per cent.), showed that these two washes at the strengths indi-

cated, as well as another (Chafers No. 1 Winter Wash, 10 per cent.), protected Plums completely from the Leaf Curl caused by Aphis, and that both Carbokrimp and Mortegg prevented damage to Apples by the Rosy Apple Aphis. They proved effective also in reducing almost completely attacks by the caterpillar of the Winter Moth. The very thorough trials recorded in the *Bulletin* to which reference has already been made, appear to demonstrate conclusively that eggs of Aphides, Apple Suckers, Winter Moth and Tortricids are killed by either of these washes at strengths of 4 to 8 per cent., but in view of the fact that a higher strength is necessary to kill Capsid Bugs, a 7½ per cent. solution should generally be employed. Provided that the fruit trees are dormant, no damage will be done by solutions of this strength. Another condition for success is that the spraying should be done when the trees are dry. If they are wet the strength of the solution used in spraying them will, of course, be reduced, and as a consequence control of insect pests may be incomplete. Needless to say, spraying must be thorough and in particular must include the tips of the shoots, for it is on them that insect eggs are frequently deposited. But, after all, insect pests are not the only trouble against which those who grow fruit have to contend. This year, for example, has often seen the few Pears which have grown to full size distorted, split and blackened by Scab. Nor have Apples by any means escaped. In order to control this disease (caused by species of the fungus *Venturia*) the practice of spraying with lime sulphur or other suitable fungicide must be followed annually. When lime-sulphur is used it may be accompanied by lead arsenate, and the mixed spray put on the trees (Apples) just when the blossom is showing pink. Those who have the necessary resources may be able to spray a second time after the fall of the petals, but, generally speaking, if the cultural conditions are good, spraying once before the blossom buds burst will suffice to secure clean fruits. The results of spraying fully justify the labour involved, and where, as so often happens, a large proportion of such fruits as are formed are malformed by attack of insect or fungus, the gardener has only himself to blame if he does not first attend to cultural conditions and afterwards supplement his labours in this direction by adopting the routine of spraying which we have recommended. Where Peaches and Nectarines are grown out-of-doors the spraying of most importance is that which is done just before the blossom opens, and for this work Burgundy mixture is, perhaps, the best spray material, although lime sulphur does almost as well.

"The Gardeners' Chronicle" Almanac for 1928.—Our Almanac for the ensuing year, giving the dates of the principal flower shows in Great Britain and of the meetings of horticultural and botanical societies, is now being prepared and will be published in an early issue of the New Year. Secretaries of horticultural, botanical and other societies are requested to send the dates of their shows, meetings, etc., so soon as possible, in order that they may be included in the Almanac.

Covent Garden Market and the Christmas Holidays.—The addition of one day to the Christmas holidays, due to the proclamation of an extra Bank Holiday, has given rise to a curious position in connection with Covent Garden Market. It appears that when, in 1661, Charles II granted the Earl of Bedford a charter to "hold and keep" a market in Covent Garden for the buying and selling of "fruits, flowers, roots and herbs," he made a condition

that the market should be opened for ever on every day except Sundays and Christmas Days. However, the Covent Garden authorities, after consultation with their tenants, have agreed to close the market on December 26 and 27; consequently, for the first time in its long history the famous market will be closed for three consecutive days—the 25th, 26th and 27th.

Holland Park Hall.—It would appear that, whether or not the Royal Horticultural Society's new hall is finished by next autumn, the Society will be unable to hold any further exhibitions at Holland Park Hall, as we understand this building is being taken over by a well-known firm of motor engineers.

Snell Memorial Medal.—On the occasion of the annual meeting of the Fellows of the National Institute of Agricultural Botany, which was held at Cambridge on the 2nd inst., Sir Daniel Hall, Chairman of the Council, presented to Sir Matthew Wallace, the John Snell Memorial Medal for 1926.

Acreages of Crops of Immune Potatoes in Scotland.—The following is a summary of acreages of Potato crops of the immune varieties inspected for purity in Scotland during 1927. The first three sets of figures in each case indicate the acreage showing a given percentage of purity, and the fourth set the total acreage:—Kerr's Pink (99.5 per cent and above), 8,791; (below 99.5 per cent to 97 per cent.), 1,446½; (below 97 per cent.), 283½, total, 10,521½; Great Scot, 6,723½, 1,278½, 722½, 8,724½; Majestic, 6,800, 899½, 376½, 8,075½; Golden Wonder, 1,670½, 62½, 14, 1,747; Ally, 1,370½, 65½, 12½, 1,449; Arran Consul, 498½, 6½, 5, 509½; King George, 413½, 31, 4½, 449; Tinwald Perfection, 221½, 56½, 6½, 284½; Rhoderick Dhu, 216, 21½, 5½, 242½; Arran Comrade, 206½, 20½, 13½, 240½; Abundance, 87½, 10½, 15½, 113½; Witch-hill, 94, 5½, 3, 102½; Bishop, 89½, 11, ½, 100½; Crusader, 82, 2½, 1, 85½; Arran Victory, 79, 5½, ½, 84½; Immune Ashleaf, 58, 1½, ½, 60; Catriona, 50½, 1½, 6, 57½; Dargill Early, 49, 0, 2½, 51½; and others, 255½, 37, 21½, 314. Grand Totals: 27,756½, 3,963½, 1,494½, and 33,214½.

French Horticultural Apprentices.—After considerable efforts on the part of the organised nursery trade in France, horticulturists have succeeded in persuading the French Ministry of Agriculture to recognise and organise apprenticeship in agriculture and horticulture, and a Central Committee has been created for this purpose by the Ministry in Paris, as well as a departmental committee in each Department. The apprenticeship of young lads will probably be on the following lines: They will apply in the first place to the Service Agricole of their own Department, but will have a choice as to where they will work, and they will go for two hours weekly to an apprenticeship establishment, where they will be taught the elements of their trade in a methodical way by professional horticulturists or head-gardeners. So soon as their names have been received at the office of the Service Agricole, they will be given a certificate of apprenticeship. After studying for a certain period, the lads will enter for the first of three examinations, which will in turn give them the status of assistant gardener, gardener and head-gardener, respectively.

Roadside Trees.—It is a pleasure to learn from a statement issued by the Ministry of Transport that the planting of trees is being extended along the arterial roads of greater London, principally in the counties of Middlesex, Hertfordshire and Surrey. Along the new by-pass roads in Kent, experiments are being conducted with fourteen different kinds of trees and these experiments will be followed with great interest by arboriculturists. In east Suffolk and in Northamptonshire, trees are being planted along the principal main roads, while treeplanting schemes have been arranged by many county boroughs in the north of England. In Swansea, Cardiff, Bristol and Plymouth, similar schemes are being carried out and the planting of trees is proposed in most places where roads are being widened.

Pot Plants for Christmas.—Cultivators of flowering plants for the supply of Covent Garden Market are unusually busy just now, as provincial buyers are sending in orders for the purpose of securing supplies for the Christmas season. Many hundreds of thousands of plants have been dispatched this week and many more will follow during the early days of the coming week. Few growers are such successful cultivators as the market men, among whom such firms as those of Ladds, Sweet, Relfe and Mills occupy a foremost position. The principal subjects offered are Heaths, all superbly grown and represented by tiny plants in thumb pots up to big specimens in 32's. *Erica gracilis*, *E. nivalis*, *E. hyemalis*, and a smaller quantity of *E. melanthera*, make a fine show in the various stands and warehouses. Chrysanthemums also constitute a large item, while *Begonia Gloire de Lorraine* and *B. Mrs. Peterson*, with its bronzy foliage, are contributed in excellent condition. Cyclamens and Cinerarias are equally good, while *Lilium longiflorum* and Poinsettias are also offered in pots. Hyacinths made their appearance about a week ago and large quantities are promised for next week. These are the large-flowering varieties and quite independent of the Roman Hyacinths grown in small boxes in the same way as the scarlet and yellow Tulips. Solanums, with their scarlet fruits, are also popular, and those grown in sixty-sized pots appear to be even more popular than those grown in 48's. There is a large demand at this season for non-flowering plants, consequently growers are sending in thousands of Palms of various sizes, Ferns in many sizes and great variety, Araucarias and Aralias.

Chelsea Trees Respited.—Trees in London, and, indeed, in every other town, are precious things, and not to be lightly cast away, so we are glad to learn that the authorities have decided to stay their hands in regard to the old trees in Cheyne Walk, Chelsea. At the moment, opinions differ as to the safety or otherwise of these old trees, and until this is settled it is surely well to allow them to stand. A tree that from age or any other cause has become a danger should, as a matter of course, be at once removed. We are also glad to learn that if the old trees are removed it is intended to plant new ones.

Aalsmeer Flower Show, 1928.—To inaugurate the opening of a new and large flower market in Aalsmeer, Holland, a big exhibition is being arranged to take place on April 17 next. Those who have visited the quaint little town of Aalsmeer know that its prosperity depends upon the cut flower industry it has developed. Forced Lilac, Roses, Dahlias, Chrysanthemums, Cyclamens and Hydrangeas are a few of the subjects cultivated extensively and well at Aalsmeer. There are already two auction markets where the flowers are sold to buyers who dispatch their purchases to all parts of Europe. The sales are conducted in the usual, quiet, Dutch-auction fashion, and are invariably interesting to a British visitor and especially to one who has a knowledge of the conduct of business in Covent Garden Flower Market. We believe the new market is the third to be erected. It has a floor space of 2,500 square metres. Only Aalsmeer florists and exporters will be allowed to take part in the general exhibition in April, but novelties will be accepted from other countries than Holland, and will be heartily welcomed. It is only in regard to novelties, the Jury, and the Committee of Honour, that this exhibition will be of international character. Full particulars regarding the exhibition of novelties in flowers and plants may be obtained from Mr. J. C. Mensing, Aalsmeer, Holland.

Roumanian Department of Horticulture.—The Department of Horticulture in Roumania, founded by the late Professor Stefanescu, has been in abeyance since his death, its functions having been nominally taken over by the Department of Viticulture under the Ministry of Agriculture. The Department has now, however, been revived, and a Director has been appointed in the person of Mr. R. Georgian, formerly Director of Viticulture. It is largely

owing to the sympathetic efforts of the present Director of Viticulture, Professor Teodorescu, that the horticultural department has been reinstated, and Roumanian horticulturists are feeling very grateful to him for the assistance he has rendered.

Mr. Frank Reader.—Everyone who has had dealings with the Royal Horticultural Society during the past quarter-of-a-century deeply regrets that Mr. Frank Reader is retiring at the end of the year from the position of Chief Cashier. Mr. Reader has made many friends and no enemies during his long tenure of office. He has been one of the Society's best assets, for like his friend, the late Mr. S. T. Wright—so long Superintendent of the Society's Gardens at Chiswick and Wisley—he has a charming and unruffled personality. Always smiling, Mr. Frank Reader has, however, experienced domestic sorrows—known only to personal friends—that would have dimmed the enthusiasm of many a younger man. Through periods of evil and good report he has served the R.H.S. with unswerving loyalty and unfailing ability, and thoroughly earned a happy retirement; but he will be sadly missed at Vincent Square. It is because of his many fine qualities, and with

MR. FRANK READER.

the hope that his remaining years may be rendered as comfortable as possible, that a Committee has been formed for the purpose of presenting him with a testimonial. The Presidents are Sir Jeremiah Colman, Bt., and Mr. A. G. Merryweather; Mr. William Cuthbertson is Chairman; and Mr. George Monro, 4, Tavistock Street, W.C.2, is Secretary and Treasurer, and to him all donations should be sent. The members of Committee are:—Mr. P. R. Barr, Mr. E. Beckett, Mr. J. S. Brunton, Mr. E. A. Bunyard, Mr. C. H. Curtis, Mr. C. G. L. DuCann, Mr. C. Engelmann, Mr. T. Hay, Mr. G. W. Leak, Mr. Courtney Page, Mr. J. MacDonald, Mr. A. W. Metcalfe, Mr. L. de Rothschild, Mr. L. G. Sutton, Mr. P. D. Williams, Mr. E. H. Christy (President, National Sweet Pea Society), Major G. Churcher (President, National Gladiolus Society), Mr. H. T. Mason (President, British Carnation Society), The Hon. Sir John H. Ward, K.C.V.O. (President, National Chrysanthemum Society), and Mr. H. R. Darlington (President, National Rose Society). Mr. Reader was born "on the land," and in his youth became a teacher. The late Rev. William Wilks induced him to relinquish that career and take service with the Royal Horticultural Society in 1890. Mr. Reader has therefore, been with the Society for nearly thirty-eight years. He has assisted in developing its Fellowship from 1,000 to 25,000, and its income from £3,500 to £56,500 annually. Although Mr. Reader has been Chief Cashier to

the Society, he has also been much more—a friend and helper to every Fellow and every exhibitor who required help. Whether it has been a member of the Council, a humble Fellow up from the country, or a fretting exhibitor who was in trouble—he has been treated kindly by Mr. Reader and made to feel for the moment that his particular case was the only one! It is to consider these services, which have been accepted for all these long years, but never publicly acknowledged, that the present Committee has been set up, and everyone who has been asked to join it has regarded the invitation as an honour and a privilege. The case for acknowledgment is more than clear in the mind of every horticulturist who has come into contact with Mr. Reader, and we feel sure, by the voluntary response already made (£165 to date), that a very handsome sum will be forthcoming. This testimonial is, of course, independent of anything the R.H.S. does for Mr. Reader, who has merited every honour and recognition the Society can bestow.

Horticultural Exhibition at Bremerhaven.—The Bremerhaven (Forth Germany) horticultural exhibition, which took place this year in September, coincided with the centennial festivities of the town, and was a great success. The exhibition, which was held in the new Town Hall, demonstrated afresh the great interest taken in gardening by the local amateurs, and in order to enlarge the scope of the show, small holders were invited to bring evidences of their industry and skill. The florists' section was also very attractive.

Royal Caledonian Horticultural Society.—The latest issue of the *Transactions* of the Royal Caledonian Horticultural Society (Vol. 11, Part 3) is of more than usual interest as it contains a particularly useful account of "Horticulture in Public Parks," by Mr. W. W. Pettigrew, Chief of the Manchester Public Parks Department. Other articles deal with "Waste and its Prevention," by Mr. W. J. Thomson; "The Rock Garden," by Mr. F. Fanner; "A Survey of the Fruit Range," by Mr. W. E. Murray; "Grasses in Relation to Horticulture," by Dr. W. G. Smith; and an instructive resumé of "The Educational value of Horticultural Exhibitions," by Mr. Adam Knight. The Report of the Council for 1926 is included, together with a list of the names and addresses of members.

Banffshire Field Club.—The members of the Banffshire Field Club listened recently to a delightful address delivered by the Rev. Dr. Bruce, retired parish minister of Banff. Dr. Bruce, who was in a reminiscent mood, dealt particularly with the beginnings of the Banffshire Field Club, pointing out the intellectual benefits the members derived from such an association. They learned of the life of the frog, the work of parasites, the fertilisation of the egg, the habits of the cuckoo and the tern, the wonderful annual migration of swallows, redwings and fieldfares. Intensely attractive to them was the biology of the seasons, with the wonderful periodicities of spring and its inrush of new life, filling the ditches with millions of tadpoles, and the hedges with thousands of nests; of summer and the great preponderance of reproduction and its lovely pigmentations; of autumn and its seed scatterings and showers of gossamer; and finally of the secrets of hibernation in winter of moles and squirrels. He referred to the great minds who led the way forty-six years ago when the Banffshire Club was formed. Sheriff Scott Moncrieff was the first President, and Mr. James Spence, English Master at the Academy, the first Secretary. With these were such stalwarts as Dr. Ramsay of the *Banffshire Journal*; Dr. Milne, Schoolmaster of King Edward School; and Dr. Cramond, the distinguished antiquarian of Cullen. Their first excursions were mainly geological, chiefly to the cliffs, at Gamrie and Portsoy, in search of fossils and evidences of the ancient glacial period. Dr. Mackie, of Elgin, took them to see the famous Rhynie plant bed in the quarry at Auchindoir, which he discovered, and which belonged in the middle age of the Red Sandstone period. Dr. Mahood, Duff House, led them on visits to the Jurassic clays scattered along the coasts,

and brought by glaciers from the Cairngorms to Boyndie and to Plaidy. Dr. Horne, of the Geological Survey, who worked for years in the Orkneys, gave them some delightful papers, beautifully illustrated, on a singular phenomenon along the shores of Scapa Flow, which showed a dark green diabase formed by an ancient flow of lava from some old Orkney "Vesuvius." He regretted that the science of geology was less cultivated nowadays in young Field Clubs. To him (Dr. Bruce) it was a subject of undying interest. They also pursued botanical studies in those early days, and found Banffshire full of interesting species of plants. At first he himself guided excursions to the Den of Eden and the Haughs of Forglen, and to the marine flora at Macduff. Mr. John Yeats and Dr. Mahood excelled latterly in the botanical excursions and gave them weekly walks and monthly journeys to hills and dales and river banks. One summer, the Rev. Dr. Playfair, of St. Andrews, was with them for the whole of that period, and added greatly to their botanical interests. This being the annual meeting of the Club, Dr. C. S. McPherson, the Secretary, reported that the Club had had a very successful year, with several excursions to different parts of Banffshire, including Cullen House, of great historical interest. The meeting concluded with warm votes of thanks to Sheriff More, the President of the Club, who was in the chair, to Dr. C. S. McPherson, the Secretary, and to Dr. Bruce, for his admirable and most interesting address.

Glasgow Flower Show, 1928.—At the meeting of the Glasgow and West of Scotland Horticultural Society on Wednesday, the 7th inst., Mr. Joseph Dobson, the new Chairman of Directors, made an encouraging statement regarding the negotiations which had taken place with the Kelvin Hall Committee regarding next year's flower show. The proposed arrangement is similar in its chief details to that which existed in 1925. Briefly, it means that the Corporation will provide the prize money, and the Society will undertake the work of preparing the schedule and arranging the exhibits. The Committee's suggestions have to be endorsed by the Town Council, but Mr. Dobson entertained little doubt that the show would be promoted jointly by the Society and the Corporation.

Mr. James Cairns.—The many friends of Mr. James Cairns, who has presided over the gardens of the Earls of Wharfedale, at Wortley, near Sheffield, for the past twenty-five years, will be pleased to hear of an improvement in his health. Mr. Cairns recently underwent a serious operation, and the result has so far been satisfactory.

Balkan Flora.—On Thursday, December 8, at a meeting of the Dublin Naturalists' Field Club, Dr. R. Lloyd-Praeger gave a most interesting and entertaining address on "Botanising in the Balkans." The main object of his visit to the Balkans was to make an exhaustive study of the genus *Sempervivum*, although, naturally, many other objects of interest arrested the attention of this keen observer. Pointing out the resemblance of the Swiss and Bulgarian floras with regard to genera, he noted that the species differed in the two countries. Plant migrations from the east, it was stated, had centred in the Balkans, whence a re-division had taken place, making this area, as it were, a botanical clearing house. Maidenhair Fern was found growing in but one spot, and that on the only place where moist limestone rock was to be found. After many references to places of interest visited, difficulties of travel, and unsuitable accommodation on such an expedition, in which for the greater part of the time he was accompanied by Mr. W. B. Turrill, of Kew, the lecturer concluded with an interesting account of the return journey, by air, and the landing at Croydon.

Appointments for the Ensuing Week.—**MONDAY, DECEMBER 19:** Birmingham Gardeners' Mutual Improvement Association's lecture. **WEDNESDAY, DECEMBER 21:** Royal Gardeners' Orphan Fund meeting; Sheffield Chrysanthemum Society's smoking concert.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Vine Culture and Wine making in South Australia.*—A friend who is thus engaged gives me some interesting particulars of his practice in that fine climate. Alluding to the endless variations caused by climate on the Grape, he says that those of Andalusia have such an excess of saccharine matter that the manner in which they push the fermentation would change the more delicate Grapes of France to vinegar. Their climate (South Australia) resembles Spain in its general temperature, and its greater aridity tends to produce even a richer juice than that of Spain. Their most

erecting a place for storing it, to ripen quicker, expecting to have it as ripe in two years as in four by the ordinary process. He carried out a great variety of the best plants collected in France, Spain and Madeira, but intends to graft most of them with the Verdulio. He makes also a red wine, of a mixture of claret and Roussillon Grapes, which at one-year old sells at 5/- per gallon. Their highest fall of rain since 1839 was 30.63 inches in 1851; the lowest 17.05 inches in 1841. The highest previous to 1851, was in 1846, 26.84 inches. *J. Stewart Hepburn, Colquhalzie, Auchterarder, Perthshire. Gard. Chron., December 18, 1852.*

FIG. 224.—CARNATION MELCHET BEAUTY.

R.H.S. Award of Merit, Nov. 29. Flowers chocolate, faintly striped with vermillion. Shown by Messrs. Stuart Low and Co. (see p. 452).

productive Grapes are of poor quality; and even a good Grape-grower on a rich alluvium will yield a good crop of superior wine to that grown on a dry stony hillside. The general practice there is to consider quantity rather than quality, which he thinks wrong, as their poor wine will be unsaleable, besides the loss from the high price of casks there. The Grape in cultivation is the Verdulio (Madeira) and the wine decidedly a Madeira, requiring the same treatment to ripen it—a high temperature and agitation. (I lately tasted some of the wine, the most delicious I ever drank). It is high flavoured, and sweeter than common Madeira. He is

Publications Received.—*A New Orchard and Garden*, by William Lawson, reprinted from the third edition; The Crescent Press, Ltd., 11, Fitzroy Square, W.; price 12/6.—*Gardening in Practice and Theory*, by F. The Week's Work.

THE ORCHID HOUSES.

By J. T. BARKER, Dunstable, Bedfordshire.

Sophrontis grandiflora.—This delightful Orchid is now in bloom, and as its brilliant flowers are always admired those who are fortunate in possessing fine varieties should take great care of them, as they will be of great value as time passes, because the species is not imported now in quantity. As the flowers are produced on the partly-made pseudo-bulbs, care should be taken that no water lodges in the crown of the growth as it may set up decay, both of the flower and the growth. When growth is complete, the plants should be allowed to rest in a cool house, where they may remain during their flowering season, but even then they must not be allowed to suffer for the lack of water at the roots. Plants in need of new rooting-material should not be potted until the longer and brighter days arrive and fresh roots are developing from the new growths.

Sophrontis Hybrids.—The hybrids of *Sophrontis* are numerous; some are of small growth and others quite large. They have no particular season of flowering as, owing to the different parents used, one or the other of the hybrids is always in bloom. In a group of plants of such varied parentage it is obvious that there is much diversity constitutionally. Some are considered to be bad growers, while others are free and robust. The majority thrive in a light, warm position in the Cattleya house, while the *Sophrontis* parent delights in the temperature of the cool or intermediate house. The hybrids are best grown suspended beyond the reach of water from the syringe and where they may enjoy all the light possible. They should be watered judiciously at all seasons, as the young growths decay and turn black if the compost is watered indiscriminately. Some of the hybrids have fine roots, and others thick ones; the latter, as a rule, are of a more robust nature than those with finer roots, therefore they may be grown in larger receptacles and the rooting-medium may be used in a coarser and rougher condition. Over-potting must be guarded against, as even the most robust growers are not capable of pushing their roots through thick masses of material. In most cases the flowers are vividly coloured, but some have flowers of a yellow hue. The repotting of any of these hybrids is best deferred until the spring.

THE KITCHEN GARDEN.

By R. H. CROCKFORD, Gardener to THE RT. HON. LORD WAVERTREE, Horsley Hall, Gresford, N. Wales.

Asparagus.—Where very early dishes of this much esteemed vegetable are required, forcing should now commence. Stronger crowns are necessary for this purpose, and these should be lifted carefully from the open ground, or obtained from a reliable source. A temperature of about 55° is suitable for the production of good, succulent stems. Excellent results may be obtained by the use of a gentle hot-bed consisting of equal parts of manure and leaves; on this place a layer of rich soil on which to spread the roots. Cover the roots with about three or four inches of friable compost, through which the heads of the Asparagus will quickly appear. Where a forcing or a Mushroom house is available a hot-bed is not necessary as the roots force quite easily if arranged in these structures and grown under similar conditions to those already advised above. But even in such houses the crowns start much more readily if a small quantity of sweet, fermenting material is used. The soil should always be kept in a moist condition, and warmed water used at all times. Keep a sharp look out for slugs and woodlice, as these pests are particularly fond of the young, tender shoots. When the growths appear above the soil they should be lightly sprayed daily with tepid water.

Hot-beds.—Where manure and leaves are available these should be thrown together in a heap to heat, and turned twice at intervals of about ten days so as to be in a suitable condition by the New Year, when a start should be made to form the necessary hot-beds for growing early vegetables and salads, such as Carrots, Radishes, Lettuces, early Peas, and Potatoes.

General.—During very bad weather, when work is impossible outside, the root-store should be examined and all specimens showing signs of decay removed. All tools should be overhauled and oiled, especially those that are now not frequently in use. Pea and Bean sticks may be prepared and tied into bundles of various sizes. Labels may be made and painted, seed Potatoes set up in trays and placed in a light, frost-proof place, so that the sprouts become sturdy by the time the sets are required for planting. Such jobs as mending and making seed and cutting boxes may all be done at these times. Soils, etc., may also be mixed in readiness for seed-sowing, thus saving valuable time when the busy season comes along.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to SIR CHARLES NALL-CAIN, Broomfield Hall, Hertfordshire.

Cool Greenhouse Plants.—*Schizanthuses*, *Clarkias*, *Godetias*, or any annuals that are being grown to produce flowers during the early spring, should be transferred to larger receptacles when rooted sufficiently to allow the work to be carried out forthwith. All these are excellent plants for the amateur to grow or, indeed, for anyone who can find room for them, for the cooler they are grown the better will be the results. Grown under these cool conditions, however, great care must be taken in watering them, and the house or frame should be ventilated freely on every possible occasion.

Lapagerias.—Now will be a suitable time to unfasten the growths from the roof wires, thin them out and thoroughly clean and carefully tie up the remainder. *Lapagerias* give the best results when grown in a restricted border; if the roots are allowed to ramble at will, many strong suckers may appear where they are the least expected, and others are destroyed by slugs, which are very partial to the young shoots. An excellent compost for *Lapagerias* consists of good medium loam and rough peat, with sufficient coarse sand added to render the compost open, but where a top-dressing only is necessary the compost may be used in a finer state. Where the compost has to be renewed the work should be done before the plants are trained into position.

Hoya carnosa.—This will need much the same treatment as that recommended for *Lapagerias*. It will flower most profusely when grown in a restricted border and fed liberally when the flower trusses appear.

Allamandas.—These stove or warm greenhouse subjects should be pruned, cutting the shoots back to three or four eyes. Where insect pests have been troublesome, the remaining growths should be cleansed with an insecticide. After pruning, the roots may be kept comparatively dry until new growths are forthcoming.

Salvia splendens.—As these plants pass out of flower they should be cut slightly back for the purpose of obtaining strong shoots to be used for cuttings. Save only those plants that have not been used for grouping in the mansion. *Salvia splendens* is frequently attacked by red spider, and the pests should be kept in check by spraying the plants occasionally with XL All.

General Remarks.—At this season of the year plants need all the light available, therefore the roof-glass in all the plant houses should be kept clean. In gardens situated near large towns it will be necessary to wash the glass at frequent intervals, especially after fog. The interior of these houses should also be cleansed and the walls lime-washed.

HARDY FRUIT GARDEN.

By H. MARKHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet, Middlesex.

Sweet Cherries.—The pruning and regulating of the branches of sweet Cherries should be completed before the weather becomes very cold and frosty. The treatment differs from that given Morello Cherries, as they fruit upon spurs and young, two-year-old wood. Keep the main fruiting bunches sufficiently far apart to allow free access of sun and air during the growing and fruiting season. If the trees were given proper cultural treatment during the past summer, very little pruning will be needed now beyond shortening spur growths and the young shoots required for extension or to replace faulty branches. Take care not to damage the bark when securing the branches, and see that all old ties are relaxed as a prevention against gumming. Choice Cherries deserve attention and good wall space; on western aspects the fruits attain a large size and are easily protected from birds.

Cordon Trees.—Cordon trained trees bear very heavy crops of large fruits when carefully attended to in the summer months in regard to pinching the fore-right and other shoots not required for extension. If the trees are planted eighteen inches apart in soil containing plenty of lime and brick rubble, and made moderately firm, growth will be strong and should soon produce good fruits.

Apricots.—When pruning Apricots, cut back fore-right growths to two or three buds, and endeavour to secure a large number of fruit buds and spurs as close to the wall as possible. Lay in young shoots as may be required for filling up gaps and to replace any of the branches that show signs of gumming. Young trees that may have made very strong growths should have their long leading shoots shortened back to the firm and better-ripened portion. In some cases the roots should be lifted and replanted. When preparing stations for new trees use good, turfy soil, old mortar-rubble and burnt earth. The soil for Apricots should not be too heavy and rich.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to COLONEL SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Pot Vines.—If the buds on the early vines are developing, the temperature may be advanced to 55° on cold nights, and 60° on mild ones, but the latter figure should not be exceeded until the vines approach the flowering stage. When the leaves begin to unfold, discontinue syringing the vines, and supply atmospheric moisture by turning the fermenting material (which will soften the effects of fire-heat), and by sprinkling water on the paths and borders every morning. Guard against spilling water on the hot pipes, as this produces a cloud of steam that is prejudicial to the young foliage. So soon as the bunches commence to open their flowers, the temperature may be raised to 65° at night and 75° by day, with an advance of a few degrees when the sun breaks through. Atmospheric moisture should then be slightly reduced and advantage always be taken of the maximum temperature for fertilising the flowers. When set and swelling, the bunches on each vine should be reduced to five or six, if good, and to seven or eight if small, when thinning may be proceeded with. From this time forward, rich top-dressings and generous feeding will play a very important part in carrying the Grapes to early maturity. To this end the stimulants should be gradually increased in strength and quantity. In the management of laterals, the object should be a full spread of healthy foliage; all shoots, as a matter of course, will have been stopped at the first joint beyond the bunch, and if any space is left, leading laterals should be tied down, while minor laterals may be pinched and regulated in the ordinary way. Vines started this month require similar treatment to those started last month.

Grapes.—Grapes still hanging on the vines should be examined frequently and have all decaying and mouldy berries cut out. The night temperature in such houses should be kept at about 45°, and when the weather permits of it being done, liberal ventilation should be afforded, but in wet, foggy weather the ventilators are best kept closed. Examine the Grapes in the Grape-room at least once a week, and keep the temperature about 43°.

Late Vineries.—Prune and cleanse late vines, removing the top soil of the border down to the roots and re-surfacing with sound loam, lime rubble, bone-meal, and a little vine manure. Examine the borders and afford water if necessary. Keep the house cool and airy to ensure so long a rest to the vines as possible. Select shoots of medium strength for making vine eyes and lay them in soil at the foot of a wall for the present.

THE FLOWER GARDEN.

By JOHN COUTTS, Assistant Curator, Royal Botanic Gardens, Kew.

General Remarks.—With the advent of the New Year, it will be necessary to commence propagating stocks of plants for summer bedding, and for this purpose stock plants should be introduced to a warm house, where they will be encouraged to make fresh growth to provide a supply of cuttings. They include Fuchsias, Heliotropes, Abutilons, Iresines and many other plants usually used for summer bedding. Where it is desired to raise quantities of plants from seeds, there should be no delay in ordering the necessary supplies, as it is essential to sow many of them towards the middle of January. These include such popular subjects as Begonias, both fibrous- and tuberous-rooted varieties. The fibrous-rooted section, as represented by the many fine *semperflorens* varieties, is deserving of more general cultivation, as there are very few plants so indifferent to varying weather conditions. *Verbena venosa* is easily raised from seeds and should be more generally used, either alone or in combination with grey-foliaged plants, or the pale yellow *Calceolaria amplexicaulis*. The many fine varieties of florists' Verbenas should also be more generally grown, as they are easily raised from seeds.

Work in Bad Weather.—During wet and inclement weather opportunity should be taken to prepare and paint flower stakes, tying them into bundles of different sizes ready for use during the coming season. Branching sprays of Hazel, or similar material, should not be overlooked for use in supporting slender-growing herbaceous plants; such material is more suitable than ordinary flower stakes, for if inserted early, the shoots will grow up through them and arrange themselves in a natural manner. Continue to collect leaves, but do not allow them to lie in heavy drifts and spoil the grass. Turn over leaf-soil and compost heaps, for the more frequently they are turned, thus allowing air to get in, the more quickly will they decay and become fit for use. Heaps of garden rubbish should receive a dressing of lime. All ashes resulting from the burning of woody rubbish should be secured while dry and kept under cover. Lawns should be swept and rolled as weather and surface conditions permit.

Crinums.—Several species and varieties of *Crinum* are generally hardy when planted in warm borders at the foot of walls; they include, among others, *C. longifolium*, *C. Moorei* and its variety *album*, also *C. Powellii* and *C. Powellii* var. *album*. The last two are undoubtedly the best for general garden purposes, and in the south, at least, are hardy in the open border. Where suitable conditions admit of their cultivation, they should be more generally planted, for they flower in wonderful profusion over a long period, and apart from their decorative effect in the garden, they are excellent as cut flowers for house decoration. They are strong-growing plants, requiring a deep root-run and rich compost. If the natural soil is not good, the planting sites should be excavated

to a depth of three to four feet, placing a layer of rough material in the bottom to afford ample drainage, for during their growing season *Crinums* enjoy ample supplies of water at the roots.

Amaryllis Belladonna.—Of this fine plant there are several varieties, varying in their period of flowering and depth of colour. These may still be planted in well-drained soil, at the foot of a warm wall. In their season they are very beautiful and invaluable for a supply of cut flowers. The usual advice to plant them at least eight inches in depth is quite wrong, for unless the bulbs are near the surface they fail to flower; the same observation applies to *Nerine Bowdeni*, which flourishes in similar situations. The writer has known several plantings of these subjects fail to flower owing to their being too deeply planted.

Fatsia japonica.—Commonly known as *Aralia japonica*, and a popular pot plant for market, *Fatsia japonica* is much hardier than is usually imagined; it is a very handsome evergreen, which succeeds perfectly in and around London, growing well in open or partially-shaded places. It makes huge specimens, and when it produces its large panicles of ivory-white flowers towards

and everything made clean and tidy, leave the ventilators open night and day until the date on which it is usual to close the house.

Broccoli.—Supplies of these are at present restricted, but where a late autumn variety, such as Sutton's Protecting, is grown, good heads are still available if care has been taken to cover the hearts of the plants with their own foliage during frosty weather. Well-grown plants of Early White on a west border are now showing a few hearts also, and a weekly run through them, closing all, or most, of their outside leaves over them, keeps them safe from several degrees of frost as well as cleaner than they would be if exposed to the light. In colder districts it is a good plan to "heel over" the later varieties of Broccoli, with their heads to the north, and partially cover up the stems with soil in the process, as this method prevents the stems from suffering during hard frost and shades the younger foliage from the strong sunshine that often follows frost; but in the milder western districts this is not necessary, as we rarely experience frost severe enough to do the Broccoli crop any harm.

Chrysanthemums.—The great annual display made by these most valuable winter-flowering

FIG. 225.—*ROSMARINUS OFFICINALIS* VAR. *PROSTRATUS*, AT LA MORTOLA

(see p. 483).

the later half of October and in the beginning of November, it presents a striking effect. Where it is hardy it should be more generally used for planting. It may be raised from seeds, ordinary cuttings and root cuttings.

FOR NORTHERN GARDENERS.

By A. T. HARRISON, Gardener to the MARQUIS OF AILSA, Culzean Castle, Maybole, Ayrshire.

Early Vineries.—The early vines should be pruned, cleansed and made ready for another season, and on the thoroughness with which the cleansing process is carried out will, to a great extent, depend the success of next season's crop. Where mealy bug is present no efforts should be spared to rid the house of this insect, as its effects are so repulsive on both foliage and bunches that the latter are sometimes rendered unfit for use. Fumigating with hydrocyanic gas at intervals, while the vines are dormant, has done much to reduce this pest, but it is so tenacious of life that it seems to evade all attempts at extermination. Its destruction may be carried on later by touching each spot of white, woolly matter with a small brush dipped in methylated spirit and endeavouring to avoid re-infection from other houses. When the border has been top-dressed

plants is again drawing to a close, and although a number of late varieties keep up the display for a few weeks longer, preparations must be made at an early date for next season, and cuttings of varieties required for large blooms inserted so soon as they can be procured. The many charming varieties of Singles and Anemone-centred varieties are most useful as cut flowers and have now gained a place in nearly all collections, as these, along with naturally-grown Japanese and Incurved sorts are more easily managed than the large, disbudded blooms. Cuttings of the Singles and Anemone-centred varieties should be taken when available, but in their case the time is not so urgent, and quite useful plants of most varieties may be grown from cuttings inserted in February or March. Last season, cuttings of Framfield White, grown and flowered in pots, were put in early in January and grown on in the usual way, while more cuttings of the same variety which had been grown and flowered in the open border were inserted during the first week in March. The latest inserted cuttings flowered several weeks ahead of the pot-grown ones; in fact, they were nearly over in the outside border, before the others, which in due course had been transferred to a cold house, were showing colour, thus proving that the earliest cuttings do not always flower first.

ALPINE GARDEN.

SOME DWARF CISTUSES.

Cistus Clusii is one of the dwarfest of the *Cistuses* and one that might be more often seen in rock gardens. It is a very distinctive little shrub with small, narrow, leathery, dark green leaves, and a stature that does not often exceed twelve inches. The habit, moreover, is compact, and the cup-shaped, white flowers, about one inch across, and with a glow of yellow at the centre, are yielded in extraordinary abundance. This is always the first of the *Cistuses* to come into bloom with me, flowers often appearing in mid-April, and a succession is maintained throughout the spring and the greater part of the summer. *C. Clusii*, in my experience, is quite as hardy as any of the more reliable species.

If rather more tender than the foregoing, *C. florentinus* never suffers any serious injury here, provided it is in poor, gritty or rocky soil. Said to be a natural hybrid between *C. monspeliensis* and *C. salvifolius*, this shrub partakes of the character of both parents, the leaves being long, narrow and dull green, with a good deal of down on both sides, especially when young. The wood and foliage of the year have also the stickiness of *C. monspeliensis*. The white flowers, which appear from midsummer onwards, are much like those of *C. salvifolius*. This hybrid does not usually exceed three feet, and in a fully exposed situation will often assume a more or less trailing habit which is delightful in the rock-garden.

C. salvifolius may also be included among the dwarfer species. It is not generally seen much above two feet, and is characterised by a peculiarly compact, shrubby habit. The rounded, Sage-like leaves are a pale, downy green, and the prettily-cupped, white flowers one inch across, have a yellow stain at the base of the petals. The stature and habit of *C. salvifolius* will vary considerably according to conditions, both in the garden and on its native hillsides along the Mediterranean. In some parts of southern France I have seen this species covering rocky knolls in the open and under the shade of Pines, with a close, prostrate carpet of growth no more than three inches in depth, the effect when covered with bloom suggesting Burnet Roses dwarfed by poor soil and exposure to sea winds. I have a number of cuttings of this carpeting form well-rooted, but it remains to be seen whether they will retain that habit in our gardens.

C. platysepalus, which has not exceeded thirty inches with me, is a remarkably beautiful species with a distinction all its own. I have not seen it in its native home, but Mr. R. C. Notcutt tells us that it comes from Crete, and that it is allied to *C. hirsutus*. It is a much-branched, twiggy shrub of compact, rounded habit, with narrow leaves fully two inches long, of a bright green, which assume a bronzy tint in winter. *C. platysepalus* is an early bloomer, often commencing before mid-May, and the terminal flower clusters yield a long succession of blossom with amazing prolificacy. The blooms, well over two inches in diameter, are pure white with a yellow basal stain. In the clarity of their whiteness, their texture and size, the flowers of *C. platysepalus* always appear to me to be more striking than those of any of the dwarfer *Cistuses*.

VERONICA CHATHAMICA.

THERE is no better shrubby *Veronica* for the rock garden than this, and for such a purpose it is one of the best of all flowering shrubs. It may not be quite as hardy as some would wish it to be, but its perfectly prostrate habit renders protection an easy matter where such is needed. Here it does not suffer to any extent from 15° of frost.

V. chathamica is an evergreen shrub, its branches being furnished with somewhat glaucous, pea-green, pointed leaves. The flowers, which are yielded profusely in cone-shaped racemes about mid-summer, are a bluish-purple, fading to almost white as they go off. While both foliage and blossoms have their charm,

the most notable feature of *V. chathamica* is its procumbent growth and the very graceful way in which the elegant branches weave their close network over bank or boulder. The plant does not seem to mind whether it is on the flat, draping a slope or mounding over rocks. Propagation is very easily effected by means of cuttings. Though I have heard of a variety called *minor*, *V. chathamica* appears to be curiously constant in habit and colouring. A. T. J.

HARDY FLOWER BORDER.

ANEMONE SEEMANNII.

THERE is about the vast majority of the plants in the genus *Anemone* a grace and beauty which readily assure them of the favour of the lover of flowers. The plants vary greatly in stature and other respects, but among all the members of the race those that may be termed the *memorosa* *Anemones* deserve and receive special admiration from many.

Our native Wood *Anemone*, *A. nemorosa*, with the other native one, *A. ranunculoides*, have been wedded, and the union has produced a very attractive flower which has been named *A. Seemannii*, although it sometimes appears in lists as *A. intermedia*, a title now bestowed upon another hybrid. But *A. Seemannii* would not have been inappropriately named *intermedia*, as in appearance it is a plant which partakes of the character of both parents. It has larger foliage than that of *A. ranunculoides* and larger flowers than those of that *Anemone*, but the flowers are of a pretty shade of yellow, lighter than those of *A. ranunculoides*. In fact, but for the colour, the prepotency of *A. nemorosa* would be very evident.

A. Seemannii has occurred from time to time in gardens where the two species were grown together, and it may be utilised in the garden for the same purposes as *A. nemorosa*. A little group is delightful during the month of May. A soil composed of loam, leaf-mould and peat will suit it admirably, and it may be cultivated in sun or, preferably, afforded some shade. It is by no means plentiful in the trade.

GENTIANA ANDREWSII.

ANDREWS' *Gentian* is known frequently as the "Closed *Gentian*," and in its native country is called the "Dumb Foxglove." Both these popular names indicate the disappointing nature of the plant. The flowers never open properly, and many who have purchased the plant without knowing this habit have been greatly disappointed when the blooms appeared and passed away without expanding. It is a plant for the mixed border where this feature is not so apparent, and where its flowers of dull blue with a white tip do not seem so disappointing as when in a position where this *Gentian* is more conspicuous. *Gentiana Andrewsii* grows from nine inches to a foot in height, and thrives in ordinary loam, in a sunny or half-shaded position. As may be expected, it is not common in cultivation, but is occasionally offered by hardy plant dealers. It may be raised from seeds or increased by division.

CLEMATIS INTEGRIFOLIA.

In a comparatively recent catalogue the non-climbing *Clematis integrifolia* was described as "very showy." I disagree with this opinion without seeking to belittle such a good old garden plant. It cannot, by any stretch of the imagination, be classed as one of the "showy" flowers. It is an erect, non-climbing *Clematis* which has been for long years in cultivation as a border plant, but has not held its own well against the influx of modern plants, and is but seldom observed in gardens, although offered in the catalogues of responsible nurserymen.

The flowers are not bright enough to be called showy, nor have they the redeeming virtue in the eyes of some—size; they are comparatively small, rather bell-shaped, drooping, of dark blue with a white centre. There is also a rare double variety sometimes listed for sale. Its height is generally about three feet, but

it may be less or more, according to the nature of the soil and the amount of moisture.

Propagation of the single variety is effected by seeds or division, and of the double by division only. I think it well to mention that the rootstock is exceedingly hard and that the plants should not be divided unless of good size. It is likely that propagation by cuttings may be performed, but I have never had occasion to try this. A good fertile loam, well enriched with manure, is the best soil for *C. integrifolia*.

Although a non-climber, *C. integrifolia* requires to be staked and tied or it will fall prostrate or nearly so. S. Arnott.

CICHORIUM INTYBUS.

THE Chicory is a native of this country, and that is probably the reason why it is so generally despised for garden decoration. This is surprising when one considers that plants with really good blue flowers are eagerly sought after. The Chicory is frequently found growing wild on rubbish heaps, in old quarries, and in stony waste places; as it grows from five to seven feet in height, it makes a handsome group in the mixed border. It is also a beautiful plant for naturalising in the wilder parts of the garden. When used for the herbaceous border it is best treated as a biennial, although plants will remain good for two years. Seeds may be sown in the open during July, but plants will flower during the first year if seeds are sown indoors during January, and the young plants placed in their flowering quarters sometime during the spring. J. Coult, Kew.

BULB GARDEN.

ALLIUM TRIQUETRUM.

THIS is a useful *Allium* for naturalising in woodland, wild gardens and stream-sides. Indeed, it has already joined our native flora in some countries. This means, however, that it is a plant to be treated with discretion where there are choicer things growing, for a species which is a good coloniser is generally a pest in the choicer company of the border. Some years ago, in a rash moment, I planted a few bulbs of *A. triquetrum* in a mixed border. It was not long before they were transferred to the wild, but I have not yet seen the end of the seedlings which this redundant Onion left behind it.

Still, in a cool woodland spot where such abounding herbs as the wild Hyacinth (*Scilla nutans*) can be given a free hand, *A. triquetrum* can be very delightful. Its tall, three-sided stems and white, campanulate flowers, with each segment lined with green, are elegant and attractive, and the grassy leafage, broad and glossy, associates well with our native herbage. The whole plant has an Onion-like smell, but like the skunk, it apparently only uses this for purposes of defence, for it is not noticeable until its owner is disturbed or annoyed.

SCILLA PERUVIANA.

THIS fine old plant seems to be "coming-in" again after a considerable period of comparative neglect, and it is well worth the attention of anyone who has a mixed border, open woodland, or space to spare between shrubs. In spite of its name, *S. peruviana* appears to be a native of Spain, and as it was introduced in the year 1607 it is a long time since it was a novelty. But, like good wine, it has lost nothing in keeping and *S. peruviana* is as hearty to-day as ever it was. In any light soil it is quite hardy enough for most places, and a plant that asks a minimum of attention.

The large bulbs throw up broad, Yucca-like leaves of a rich, glossy green, about eight inches in height, these remaining all the winter. In early summer the flowers appear in bold, pyramidal umbels some six inches or more across, the star-shaped blooms being a violet-purple. But there are varieties in several shades of colour, some approaching blue, and there is a white. *S. peruviana* can endure 15° to 20° of frost in a free soil. It is generally advisable to lift and divide the bulbs about every third year, this being done in July or August. N. Wales.

TREES AND SHRUBS.

ARAUCARIA BIDWILLII.

IN *The Gardeners' Chronicle* of September 24 appeared a note on the above-named *Araucaria*. The photograph (Fig. 226) will convey an idea of the beauty of this species, as represented by a specimen growing in the grounds of Henapyn, Torquay. It was a very pleasant surprise to me to find *Araucaria Bidwillii* growing so well out of doors, as, previously, I had only seen it growing under glass. The largest specimen I know is the magnificent one in the Temperate House at Kew, and so far as I am aware the plant figured is the only one growing out-of-doors in this country.

Araucaria Bidwillii is known as the Bunya-Bunya Pine of Eastern Australia, and was named after Mr. J. T. Bidwill, one of the early botanical explorers of Australia and New Zealand, and a correspondent of the late Mr. James Veitch, of Exeter. It is said to attain its finest development between Brisbane and the Burnett rivers, where it is often found growing to a height of 150 feet. The leaves are ovate-lanceolate and sharply pointed, convex above and concave beneath, and of a deep, glossy, green colour.

I shall watch the Henapyn tree with interest for signs of a cone. I think it only fair to add that this particular example was sheltered in its early stages from south-west gales by a large Cedar, which has since been removed. It is growing about 150 yards from the sea. *F. G. Cousins, Torquay.*

THE PROSTRATE ROSEMARY.

FEW will be other than ready to accord to this delightful plant the foremost place among the varieties of *Rosmarinus officinalis*, and most of us will gladly give it a prominent position in a list of the choicest rock garden shrubs. If it is not quite so hardy as the type, its prostrate habit, and the fact that it will be quite happy draping a vertical wall suggest possibilities in the way of protection from severe frost, which would be impracticable with tall shrubs.

This little Rosemary closely resembles the type in all but manner of growth. The leafage is rather smaller, denser and a brighter green, but the bright blue flowers are the same and these are produced in abundance throughout the spring and often well into the summer. As I have implied, this charming Rosemary is quite procumbent in habit, closely covering a bank or boulder or the face of a wall with the best of goodwill. It delights in sun, of course, and the soil and aspect can scarcely be too hot for it. The best display of this Rosemary that I have seen was at La Mortola (Fig. 225, p. 481) where a retaining wall to one side of the tennis court is entirely covered by its mantle of fresh green foliage and azure flowers.

Although the prostrate Rosemary is said to have been introduced from Capri, where it grows in company with *Lithospermum rosmarinifolium*, I feel sure that equally prostrate forms might be collected in various parts of Italy. At any rate, near Bordighera, I have seen any number of Rosemary bushes on the hills, all of which were not only dwarf in stature, but which persisted in the prostrate habit, the branches arching over and bringing their tips to the soil when about six inches high. *A. T. Johnson.*

LESPEDeza BICOLOR.

INCLUDED in several of the exhibits of hardy shrubs at the last Holland Park show were specimens of *Desmodium penduliflorum*, a species now referred to *Lespedeza bicolor*.

This and *L. Sieboldii* appear to be the only species in common cultivation in this country. It is a native of northern China and Japan, and may be considered hardy in all but the most exposed gardens. It will thrive either in a mixture of sandy soil and peat, or a deep, fibrous loam so long as the site is well-drained, and when well-established in a suitable position it will grow to a height of six or seven feet.

The small, Pea-like, bi-coloured, rosy-purple flowers are produced abundantly along the graceful, drooping branches during August and

September; and in conjunction with the glabrous, pinnately-trifoliate leaves, create a most pleasing effect in the shrub border. *R. K.*

POPULUS LASIOCARPA AND
P. SZECHUANICA.

THESE two Poplars were among Wilson's earlier introductions from China, but there

trees have an open, branched habit; the main stem is greyish, with scaly bark; the branches are stout, slightly angular, hairy and dull green in colour; the leaves are firm and average three inches to six inches long and two inches to four inches broad, deeply cordate, with acute apex, extra downy, clear green above, dull green and rather rough underneath, and are margined with gland-tipped serrations. The

FIG. 226.—ARAUCARIA BIDWILLII, AT HENAPYN, TORQUAY.

appears to have been very little mention of them in the gardening press, so I presume they are not often seen in gardens.

Although the two are unmistakably different, I am afraid they are confused in some quarters. Of the two, perhaps *P. lasiocarpa* is the better known, and although good specimens may be found here and there, I have only young trees under observation, and these are decidedly interesting and distinct.

P. lasiocarpa is found in central China; young

petiole is four inches to six inches long, round, with swollen base, distinctly red in colour, as are the midrib and chief veins. The buds are large and long-pointed, viscid and curve outwards from the branch. I have not seen flowers on living plants. Young trees that were planted in sandy loam have made eighteen inches or more growth in a year, and yet under similar conditions some have failed as though cankered. The loose habit suggests that pruning, which should be done early, as the tree seems to resent

severe cuts. If neglected, the branches soon get unwieldy, sway badly in windy weather, and the tree is difficult to keep in position.

P. szechuanica is found in Western China, and is of similar habit to the former, but perhaps a little more stiff. The young growths are bright green, polished and angular, noticeably marked with lenticels; there is a little pubescence on young growths and foliage. The foliage is heavy and the handsome leaves average three inches to six inches long, two inches to three inches broad. On healthy, young trees in the nursery I have measured leaves between ten inches and twelve inches long, and exceptionally fine. They are somewhat oblong-cordate, with acuminate apex, stipulate, coriaceous in texture, dark green and smooth above, white and shining underneath; margins serrate; petioles two to three inches long, round and deep red. The chief veins are also red and this colouring is an attractive feature in these two Poplars. The buds are large, sticky, long-pointed and slightly curved. A tree planted about 1916 is twenty feet or more in height. The foliage is sufficiently distinct to distinguish *P. szechuanica* from *P. lasiocarpa*.

As with many more Poplars, there is no autumn beauty in the foliage; the leaves merely curl, turn brown and fall. I am uncertain as to the propagation of *P. lasiocarpa*, but it appears to be not easily increased from cuttings, but certain nurserymen are evidently successful with it. On the other hand, there is no hindrance to the propagation of *P. szechuanica*, and a stock may be raised quickly, as I have seen cuttings inserted in sand, under a propagating case, indoors, rooted and potted off during the month of August. Cuttings made from leafless shoots inserted out-of-doors in autumn, may be relied upon. *C. F. Coates*.

CELASTRUS ARTICULATUS.

It is somewhat surprising that this highly decorative climbing shrub is not more popular in our gardens, as at this season of the year there is no plant of climbing habit to compare with it. It is a vigorous grower, and when mature often has vines up to forty feet in length, the branches and main growths twining round each other and round anything that will give them support.

Celastrus articulatus may be used for a variety of purposes. It is effective if trained round upright poles or over walls and fences, but is perhaps most attractive if allowed to ramble over hedges or old standard trees. One of the best specimens I have seen was clambering over a large bank of *Rhododendrons*, the brightly-coloured fruits of the *Celastrus* showing to great advantage against the dark green foliage of the *Rhododendrons*.

C. articulatus is a deciduous shrub of no particular interest in respect to foliage or flower, but very ornamental when fruiting. The leaves are from two to five inches in length and obovate in shape, pointed at the apex, and narrowing to a short stalk at the base, while the small, green flowers are produced in numerous, small, axillary clusters. These are followed by round fruits which are about a quarter-of-an-inch in diameter, green at first, but turning to yellow as they ripen, and finally bursting to disclose the golden, inner surfaces of the capsules and the glossy, orange-scarlet fruits, which remain attractive from the end of October until (very often) the end of January, as birds do not seem to relish them.

This *Celastrus* is a native of north-east Asia, and was introduced to this country about 1870. It is of easy culture and is readily propagated either from seeds or from cuttings of half-ripened shoots taken during late summer, so that there is no good reason for its comparative scarceness in gardens.

PYRACANTHA GIBBSII.

ALTHOUGH several years have elapsed since the introduction of this *Pyracantha* from China by Mr. E. H. Wilson, it is still comparatively rare, and seldom seen other than in large gardens where choice shrubs are a special feature. There can be no question as to the beauty of this shrub, or its usefulness; it is one of the finest evergreen, fruiting shrubs in cultivation, possess-

ing the additional charm of being very attractive when in bloom.

P. Gibbsii was introduced as a form of the Himalayan *P. crenulata*, under which name it received an Award of Merit in January, 1925. It was then sent to Kew for identification, where it was determined as a distinct species and given its present name in honour of the Hon. Vicary Gibbs, whose keen interest in shrubs is well-known. *P. Gibbsii* is a strong, free-growing evergreen shrub, ten feet or more in height, with dark, glossy, green, crenated leaves considerably larger than those of *P. crenulata*. It is very regularly and exceptionally free-flowering, the flowers being creamy-white and borne in dense clusters on all but the oldest growths. These flowers are followed without fail by masses of round, flattened fruits, which are about a quarter-of-an-inch in diameter and of a glossy, rich scarlet colour. They are usually fully coloured by the end of November, and if untouched by birds remain attractive well into the following year.

P. Gibbsii grows quickly from cuttings of ripened shoots inserted in late autumn in an open border under a north wall or, better still, in a cold frame; the seeds germinate freely and often give rise to quite distinct forms.

Besides being a handsome subject for the shrub border, this *Pyracantha* makes an attractive covering for a wall with a cold aspect, responding well to training and never failing to flower and fruit freely. *A. G. F.*

ROSE GARDEN.

THE BANKSIAN ROSE.

Rosa Banksiae was introduced from China in 1807 and named in compliment to Lady Banks. It was at first grown under glass, but records state that in 1813 two Banksian Roses were planted in the open ground at Spring Grove, and five years later they had covered forty feet of wall.

The Banksian Roses thrive in a warm, well-drained soil, with the protection of a south wall. Flowers of the yellow Banksian Rose are small, but very freely produced in clusters. It commences to bloom in May. The foliage is shining, smooth and evergreen. The double white Banksian Rose has very fragrant flowers, produced in clusters. Another form, sometimes grown under the name of *Rosa Fortuneana*, has large, solitary, white flowers. A single, yellow-flowered Banksian Rose is very bright and attractive.

These Roses require judicious pruning. Badly ripened shoots should be removed, and also laterals which have produced flowers. Retain the medium-sized well-ripened shoots, as these will produce the earliest blooms. *C. Ruse*.

FLOWER GARDEN.

CATHCARTIA VILLOSA.

THIS interesting plant is one of the oldest of those tribes of Poppyworts and Meconopsis which have come to us from the region of the Himalayas, as it was introduced in 1850. Closely allied to *Meconopsis*, *C. villosa* is a perennial though not generally a long-lived one. It makes a tuft of heart-shaped leaves which are lobed and interlobed, bright pale green and covered with a pelt of golden fur. At this early stage, *C. villosa* might be mistaken for *Meconopsis Wallichianum*, but the branching stems, rising nearly to two feet, bear a shower of pretty, golden-yellow flowers, like small, yellow Poppies. A cool, vegetable soil, uniformly moist and well-drained, with part shade, is what *C. villosa* appears to enjoy. But even under the most promising conditions the plant will often die away, apparently from the effect of winter wet. However, it seeds freely, and this affords a ready means of increase. *J., Wales*.

INDOOR PLANTS.

LACHENALIAS.

THE beautiful colours and free-flowering habit of *Lachenalias* have brought them into prominence during recent years, and undoubtedly they are valuable spring-flowering plants. The texture and mottled appearance of the leaves are attractive, and no other flowers possess quite the same shade and waxy appearance. Another item in favour of *Lachenalias* from the grower's point of view, is that the bulbs increase with remarkable freedom under good cultivation so that frequent replenishment is not necessary.

The plants will not withstand hard forcing but for decoration in the early spring months they are invaluable. Their cultivation is extremely simple and consists in potting the bulbs in August or September in a good compost and placing them in a cold frame until growth begins. They should then be transferred to a greenhouse with a temperature of from 45° to 55°, where they will grow satisfactorily and flower from February onwards. After flowering, the plants should be kept growing until the foliage shows signs of ripening, when water should be withheld gradually, and the pots fully exposed to the sun, so that the bulbs may ripen off.

There are many excellent varieties varying in depth of colour and markings of the flower. *Leiden* is a very showy variety with large golden-orange bells, borne on reddish stems, and it is very vigorous. *Monte Carlo* has rich, golden-yellow bells, shaded with coral-red at the edge, while *Nelsonii* is a remarkably beautiful and free-flowering variety, with reddish stems that bear golden-yellow bells, slightly marked with green. *A. P. C.*

COLUMNEA SCANDENS.

IN *Columnea scandens* we have a subject of great charm in the warm house during the latter part of summer and early autumn. It is a Gesnerad, hailing from the West Indies, hence its need of heat. The tubular, scarlet blooms are an inch or so long, and when seen depending from a plant growing in a large basket, make an attractive display. I recently saw such an example at Luton Hoo, when spending a pleasant hour with Mr. Metcalfe, who speaks highly of this old stove plant.

Another way of displaying this plant to advantage is to secure the growths to pillars, up and around which they can be trained so as to give equally good results as are obtained by the hanging-basket method.

Propagation of this stove evergreen is not difficult, cuttings rooting well in sandy soil in a warm frame. Later treatment demands thorough drainage and a rooting medium of peat, loam, sand and charcoal.

There are several other members of this family, some shrubby, others climbing or trailing, and all are more or less beautiful, with orange, scarlet, purple or striped flowers, but *Columnea scandens* is one of the oldest and perhaps one of the best known. *C. T., Amptill*.

COLEUS THYRSOIDEUS.

It was good to see a reference to this excellent winter-flowering plant by Mr. Harrison in his recently weekly notes. *Coleus thyrsoideus* seems to have been overlooked or neglected by many gardeners since the war days. Yet what a fine plant it is! The rich blue flowers are, in the writer's opinion, not to be beaten in their colour by any other indoor flowering plant. They endure well, too, both in a cut state and on the plant.

Plants are not easy to maintain in perfect condition owing to their habit of yellowing and dropping the bottom leaves prematurely, thus leaving the bare stems to view. To hide this defect I place the plants between Ferns and other foliage subjects. On one occasion, when looking round a garden, the gardener in charge had put a few *Coleus thyrsoideus* among

the pink *Begonia Gloire de Lorraine*, and the effect produced was, as may be imagined, quite captivating.

Coleus thyrsoideus is a native of Central Africa and belongs to the Labiatae Order. The time of flowering is, usually, Christmas to March. Plants are raised from seeds or from cuttings and after pinching out the growths at an early stage, attain a height of three feet or more. *C. T.*, *Amptill Park*.

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM KLOTZSCHIANUM.

ALTHOUGH *Cypripedium Klotzschianum* (Fig. 227) has never been a common or popular Orchid under cultivation, it is, nevertheless, an attractive member of the *Selenipedium* group, with a close affinity to *C. caricinum* and *C. Lindleyanum*, and requires similar cultural treatment to these species.

C. Klotzschianum was discovered in British Guiana during the second Schomburgk expedition to that country, and at a later date (1885) it was found on Mt. Roraima by Mr. Im Thurn, and plants were imported by Messrs. Sanders. The wide-mouthed lip is pale yellowish-green, with distinct veins and brown spots just within the rim. The narrow, elongated petals are greenish, with a shading of rose or pink, while the long, slightly-twisted dorsal sepal is also green, with rose tinting and dark, purplish lines. The dark flower stems, the ovary, and the undersurface of the sepals are all hairy.

C. Klotzschianum flowers during the summer and is an interesting plant, but, unfortunately, it belongs to a section that is not at present popular among growers of *Cypripediums*.

YELLOW-FLOWERED CATTLEYAS, LAELIO-CATTLEYAS AND BRASSO-CATTLEYAS.

THE handsome coloured plate of *Laelio-Cattleya Oriflamme*, issued with *The Gardeners' Chronicle* of October 8, indicates the advance made by hybridists in the introduction of yellow colour to this most gorgeous family of plants.

Nature has not been lavish in her gifts as regards this colour. *Cattleya Dowiana* and its variety *aurea*, afford the best examples of yellow colouring in the *Cattleya* family, whilst the few yellow *Laelias* are either small or deficient in colour, and in the genus *Brassavola* there is not a single example.

The earlier hybrids between *Cattleyas* and *Laelias* did not show much evidence of the possible development of a race of golden-yellow *Laelio-Cattleyas*, but by continuous efforts a brilliant series has been evolved, and many of the most highly-coloured examples are interesting secondary hybrids.

C. Dowiana aurea, the predominant partner in the evolution of this group, was never a robust grower, and always very difficult to keep in a healthy condition over a series of years, even under the care of the most experienced growers.

Although the yellow-flowered hybrids are not as robust as many of the dark-flowered forms which have *C. Dowiana* as a parent, there are many of free growth and easy culture which produce their flowers in profusion at different seasons, so that their beauty may be enjoyed nearly all the year round.

Among the better-known *Cattleyas* with yellow flowers, or yellow suffused with bronze, there are *C. Aeneas*, *C. Triumphans*, *C. Iris*, *C. Venus*, *C. Mrs. Medo*, *C. Jasper*, *C. Helidor*, *C. Rhoda* and *C. iridescens*, and continual improvement is taking place.

There are many very handsome *Laelio-Cattleyas* to select from, and the beautiful *Laelia tenebrosa*, *Walton Grange* var., used as a parent, has been the means of increasing the size of the flowers in the later hybrids of this family. These include *L.-C. Luminosa aurea*, *L.-C. Thyone*, *L.-C. Witleyense*, *L.-C. Carmencita aurea*, *L.-C. Coronet*, *L.-C. Ophir*, *L.-C. Mercia*, *L.-C. Elinor*,

L.-C. Ernestii, *L.-C. Helius*, *L.-C. Nelius*, *L.-C. Myra* and *L.-C. G. S. Ball*. *Laelio-Cattleyas* are always deficient in shape as compared with *Cattleyas*, owing to the narrowness of the petals of the *Laelia* parent.

It is among the *Brasso-Cattleyas* and *Brasso-Laelio-Cattleyas* that the greatest improvement has been made, the yellow colour being imparted entirely by a *Cattleya* or *Laelia* parent. *Brasso-Laelia Mrs. M. Gratrix*, when introduced in 1899, was considered a great achievement, but compared with some of the later hybrids, it is comparatively insignificant; but this applies to all sections of Orchid hybrids. The better known hybrids of this group are *Brasso-Cattleya Mrs. J. Leemann*, *B.-C. Ida*, *B.-C.*

the flower to a bird. It succeeds best in a stove temperature when growing, but when the large pseudo-bulbs are fully made up, the drier, cooler atmosphere of the *Cattleya* house suits it best.

This species requires a long, dry rest, without which, however strong the growth may be, flowering is problematical. The application of water to the roots needs care, especially during the winter months, and it is better to keep plants on the dry side rather than afford too much water, as an excess often causes the pseudo-bulbs to decay. *J. T. B.*

GARDEN NOTES FROM SOUTH-WEST SCOTLAND.

EIGHT degrees of frost in the first week of November marred the autumnal livery of our woods, killing off the foliage of most trees before the leaves had time to brighten. Practically the only deciduous tree still well-clad in its yellow mantle is the Rum Cherry—*Prunus serotina*—which I have a personal reason for esteeming, reminding me, as it does, of my old friend, the late Mr. H. J. Elwes, who gave me seedlings many years ago; but it deserves more attention than it has hitherto received in this country as a forest tree, its timber being in much request in its native North America for cabinet-making. It owes its popular name of Rum Cherry to the use made of its berries for flavouring spirituous liquor; but none of our trees here—now from twenty-five to thirty feet high—have borne any fruits as yet.

It is a pity that Mr. Findlay had not a better specimen than the one shown in Fig. 198, page 439, to illustrate his note on *Pinus radiata*. This noble Pine, which continues to be more generally known under Douglas's name of *P. insignis*, forms a splendid bole when grown under forest conditions; nor can I agree with Mr. Findlay that it is "of little use as a forest tree." It is true that the timber is light and soft, but it is produced more rapidly than that of any other Pine, and I understand it is in much demand in New Zealand and South Africa for packing cases. The enormous consumption of timber for pulping and paper-making is supplied at present from forests in a climate too severe for *P. radiata*, but there can be little doubt of its value for those purposes if it were grown as a crop in mild, maritime districts. The superb verdure of this Pine renders it specially suitable for ornamental planting; but isolated specimens require timely use of the knife to prevent a sprawling habit.

The note upon *Saxifraga Cotyledon islandica* (page 443) reminds me of my first acquaintance with the fine variety that goes under that name, but it certainly is not entitled to it. It must be twenty years or so since I was being taken by the late Mr. Bidder round the garden of St. John's College, Oxford, which he did so much to enrich and beautify. He showed me this *Saxifrage*, which, he said, had been collected in Iceland by a friend, and he gave me a piece of it, whereof the offspring has increased and thriven here ever since. But the flora of Iceland contains no variety of *Saxifraga Cotyledon*, and Mr. Bidder told me later that the friend who collected the plant in question had changed his mind about his destination, and had spent his holiday in Norway instead of Iceland!

About this time last year, I expressed regret, I think, in *The Gardeners' Chronicle*, that I had never succeeded in getting *Sternbergias* to flower here. My complaint brought a letter from a kind lady in Kent, together with some bulbs of *Sternbergia* (I am not sure of the species) which she told me never failed to flower in her garden or to increase freely. These were planted at the foot of a brick wall facing south; they have sent up plenty of shining, green leaves, but no flowers. I should be glad to hear whether this bright autumnal *Amaryllid* ever flowers in northern gardens. *Herbert Maxwell, Monreith.*

FIG. 227.—CYPRIPEDIUM KLOTZSCHIANUM.

Miranda and *B.-C. Safrano*; *Brasso-Laelio-Cattleya Everest*, *B.-L.-C. Golden Casket*, *B.-L.-C. Winnifred* and *B.-L.-C. The Baroness*. The last-named has been the parent of many of the lovely hybrids shown recently at the R.H.S. meetings.

As improvement in these yellow-flowered Orchids has been so great during the past decade, we may hope that it will be still greater in the future.

PERISTERIA ELATA.

THIS old plant, well-known as the Dove Orchid is always of considerable interest when in bloom, on account of the resemblance of

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, W.C. 2.**

Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.

Urgent Communications.—If sent by telegraph, these should be addressed "Gard. Chron.," Rand; or by telephone, to Gerrard, 1543.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Letters for Publication as well as specimens of plants for naming, should be addressed to the **EDITORS, 5, Tavistock Street, Covent Garden, London.** Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.

MR. F. KINGDON WARD'S NINTH EXPEDITION IN ASIA.*

XXI.—THE ALPINE HARVEST.

SEPTEMBER 26: minimum 49°, maximum 58.5°; continuous drizzle. To-day work began at full pressure again, and the first thing to do was to throw a bridge across the torrent. This was more difficult than it looked, for there was a lot of water coming down, and timber was not plentiful. However, after an hour's work, we managed to jamb a large log athwart the current at a suitable point, and crossed in some trepidation—for a slip would have spelt disaster. I now went up the narrow rock gully towards the cliff where, in June, *Rhododendron megeratum* and *R. Edgworthii* had hung in magnificent bunches. *Primula eucyclia* was seeding very badly, but I secured a few capsules. Close by, I noticed a truss of capsules on the big-leaved 'Barbatum' *Rhododendron*, the first seen, and on a rock there grew a clump of the sea-blue *Gentiana Veitchiorum*, one of the 'Ornata' section, and a fine thing. In fact, there were more flowers than ripe seeds at present, and during the next few days I collected several *Swertias*, two species of *Cyananthus*, *Crawfordia*, an Orchid, *Saxifrages*, *Pedicularis*, *Mimulus*, *Polygonum*, many *Compositae* and *Umbelliferae*.

So rankly did the meadow grow now that it was almost impossible to ascend the lower portions of the gullies. In June, not only had the meadow plants not appeared above ground, but there was a great slanting, semicircle of snow to tramp up—it showed the way, offered good foot-hold, and kept one from getting entangled in the growth on either side. Now the snow had all gone, the meadow had grown up over the earth cone to such a height that it was impossible to keep one's direction, and deep water-courses overgrown with vegetation and quite invisible until you fell into them, afforded the only possible route. At higher altitudes the meadow disappeared and the gullies became exposed; but here they were steep and treacher-

ous, for water was flowing down them, the rocks had not yet settled after the scouring of the rainy season, and the smallest stone dislodged might start a crashing slide; but one had to ascend by the gullies, the face being far too steep.

September 27: minimum 45.5°, maximum 65°; weather improving. I went for a long climb, but again obtained more flowers than seeds, though the crumbling capsules of the 'Tea Rose' *Primula* (*P. Agleniana*) were ripe. There were some fine bunches of golden *Saxifrage* on the cliffs, and most of the *Rhododendrons* were seeding well, though I did not intend to start collecting them until the second week in October; still, it would not do to put it off till too late, as the snow might come at any time, though actually it did not come in serious bulk till November.

I found the high meadow composed of a large assortment of flowers, including *Geranium* (2 spp.), *Impatiens* (3 spp.), *Polygonum* (3 spp.), various *Compositae* (*Senecio*, etc.), *Astilbe*, *Valeriana*, *Saxifraga*, *Dipsacus*, *Epilobium*, a few *Labiatae* and *Umbelliferae*, Ferns, Lilies, *Nomocharis pardanthina*, *Primulas* (*P. sikimensis*, etc.), twining *Aconite*, *Cuscuta*, etc.

FIG. 228.—CLIFFS AND SCREES, WITH SNOW BEDS; 15,000-16,000 FT. ALT.

There are comparatively few grasses in this high autumn meadow, and many of the plants, e.g., *Saxifrage* and *Impatiens*, ascend to considerable altitudes, where they become much dwarfed.

One of two more loads arrived in camp, and we had sufficient food to carry on, living chiefly on Rice; but I was still very uncomfortable, without any camp furniture.

September 28: minimum 45°, maximum 71°; a fine, sunny day. The wind changed direction in the night and I awoke in the small hours to find the sky blazing with stars. After an early breakfast, I went up the cliff to look for *Magnolia globosa* and *Viburnum Wardii*. The former was more abundant than I thought, growing in the dense tangled thickets of *Rhododendron aureum* and other species, *Enkianthus*, *Acer*, *Pyrus*, *Viburnum*, etc., on the precipitous rock face. The largest bushes are twelve to fifteen feet high, and nearly as much through, sometimes two or three together, but usually scattered. I never saw more than six fruits on any one bush, and two or three were a more common sight. The fruits turn bright rosy-red, like an Apple, as they ripen, and open to expose the brilliant seeds; they average three or four inches in length. What the flowers are like I do not know, but the foliage, glistening with tawny golden hairs, is rather striking. Never-

theless, the plant is evergreen, and even if the flowers are very showy, they cannot be conspicuous, unless many more are produced under cultivation. The discovery of this species here was interesting; it was first recorded from Sikkim, and subsequently found as far east as the Salween-Taron divide, within what we have called the Indo-Himalayan region. I expect that it will presently turn up still further west, in the Assam Himalaya. *M. globosa* was by no means a common plant here, and I took particular note of its situation because I saw it nowhere but on this one very steep, bush-clad rock face, which might have been tree-clad, had there been sufficient soil.

Viburnum Wardii, which has beautiful foliage, both in summer, when the rugose leaves are dark green, and in autumn, when they mellow to volcanic reds and yellows, was common enough, but the great panicles of chalk-white flowers produce few fruits, which blacken suddenly, and disappear. They do not come adrift easily, so no doubt birds are responsible. At the lower altitudes where the tree grows it does not seem to flower at all, and I found scores of trees which never had flowered, and wasted much time searching them for non-existent fruits. Eventually I met with trees higher up which still bore a fair number of berries, though it was necessary to climb for them.

September 29: minimum 50°, maximum 61°: The fine weather was short lived, the rain beginning again in the night. Yesterday the yak came down from the alps, on their way back to the village, and the men wanted my hut. Needless to say, possession was the law, especially as they had not yet done anything about my kit; I had no oil for my lamps, no flour, no bed, or chair, or table, and only Rice and porridge to eat.

I went into the forest to collect seeds of *Magnolia mollicomata*, and picked up a few fallen cones. I also discovered several trees of *Ilex nothofagacifolia*, but not one had any berries; all seemed to be dying off at the top, and moss-shrouded and draped them in anticipation of their death and burial. People have in the past been guilty of exterminating plants—though not, perhaps, from the Burmese jungle! Here, on the contrary, is an example of the exact opposite, for this *Ilex* is, I feel sure, in a fair way to disappear in the fierce competition of the temperate rain forest, to be reincarnated in Britain from seeds I collected.

This upper temperate rain forest consists largely of *Rhododendron sino-grande*, *Magnolia mollicomata*, a 'Thomsoni' *Rhododendron*, *Acanthopanax*, the *Ilex* above-mentioned, and enormous Oak trees; the first Conifers met with are *Tsuga* and *Juniper*, and these mark the transition to Conifer forest above. In the undergrowth one meets with the same small trees and shrubs which elsewhere form the tanglewood, *Pyrus*, *Hydrangea*, *Viburnum*, *Ribes*, *Rubus*, 'Neriiflorum' *Rhododendron*, etc. There is a considerable epiphytic flora, the woody plants being mostly species of *Rhododendron* ('Maddeni', 'Vaccinioides', *R. Edgworthii*, *R. megeratum*, etc.), and *Pernettya*. Where the ground is rocky, it is covered with Ferns and creeping species of *Rubus*; elsewhere, with a thick, sodden mould of dead leaves, fruits, sticks and so forth. Climbing plants include a big *Aristolochia* and *Clematis*.

On the whole, this part of the forest is botanically interesting rather than horticulturally promising, though there is always the chance of a good new *Rhododendron*, or *Magnolia*, and the big-leaved *Pyrus*, *Viburnum Wardii*, and the best *Ilex* all came from this department.

September 30: minimum 49°, maximum 64.5°; showery, but more promising. I went for another long climb, ascending to about 13,000 feet, where I found an interesting prostrate *Lonicera* curtaining the rocks, and collected some of the juicy, black berries. Seeds of *Primula prenantha* and *P. Agleniana* also went into the bag, and about three capsules of the very rare *P. calthifolia*, a yellow-flowered species over which hangs the fog of mystery. When I first found it, in June, there was only a single specimen in flower, and so rare was it—about half-a-dozen plants—that I had no intention of taking any more. From its foliage, habit and capsule, I did not hesitate to call it a 'Nivalis';

* The previous articles on Mr. Kingdon Ward's Ninth Expedition in Asia were published in our issues of August 14, 28, October 9 and November 20, 1926, and January 1, February 19, March 5, 19, April 9, 30, June 4, 18, July 30, August 20, September 10, October 1, 15, November 5, 19, and December 3, 1927.

from its flower, Professor Wright Smith has decided that it is a 'Petiolaris,' the foliage being no bar to that decision. And a 'Petiolaris' it must remain for the present, as I have no fruits with which to upset the Professor's

almost ceased now, and the weather being clearer I could see what I was doing. From the high ridges it was now possible to see much of the surrounding country, and the mountains being clear of snow, I satisfied myself that there were

Corydalis, and even *Primula melanodonta*, flowering freely for the second time. Altogether there was enough work to keep me busy for three weeks; my two coolies, who sometimes accompanied me on these climbs, were unable to stand the biting wind on the heights, and also they were more urgently required getting up stores. I shifted some rations up to the 12,000-foot camp, against the day when we should cross the Diphuk La for the last time; and on October 9 my mail arrived from Fort Hertz. On the 18th, fifteen Taron coolies arrived, but we did not start down till the 20th, and then only went so far as the yak camp, where I spent a day collecting *Rhododendron* seeds. On the 22nd we returned to the village, and I at once set about preparations for the journey to Assam. *F. Kingdon Ward.*

FIG. 229.—*GENTIANA VEITCHIORUM* IN ALPINE TURF, 10,000 FT. ALT.
(see p. 486.)

conclusion. *Cyananthus lobatus* was in flower on the alpine turf, and a big cottony Thistle on the rocks below. I saw a Monal pheasant, and collected a number of flowers, including *Pedicularis*, *Corydalis*, *Allium*, *Gentiana*, *Swertia* and *Saxifraga*.

Altogether an enjoyable day, although I got very hungry. However, I had sent one of the men down to the village quite early, with orders to bring up some food at all costs, and when I got back to camp he had arrived with a box of stores, some flour, and some oil. Another man had gone off to Adung Long, a day's journey distant, to collect a few Nung coolies, and as several of the Tibetan herds were going up the valley I made them carry loads up to my alpine hut, whither I proposed to follow so soon as the coolies came.

On October 1, the headman arrived from the Tibetan village, and I almost came to blows with him over the subject of coolies; as a result some did arrive next day, so we moved up to my hut, at 11,000 feet, for three weeks' intensive seed collecting. I found my rock garden intact, all the dwarf, cliff *Primulas* having set seeds, the tiny *P. rhodochroa* best. The dwarf purple *Iris* gave trouble, firstly because the capsules rise directly from the ground level, and were consequently hidden amongst the herbage; secondly, because the yak had been here before me, tramping all over the grass slope. However, before darkness fell I had discovered a dozen capsules—all that was left of them!

For the first nine days in my high camp the weather continued cloudy, with drizzling rain, and showers; it was not cold enough for settled fine weather, the average minimum being only about 43° (lowest 39.5° on October 10, which was a fine, sunny day), and the average maximum about 54°. Then came a drop in the temperature, and a week of bright weather, with icy winds on the mountain heights; average minimum for seven days 34.5° (lowest 33°), average maximum, about 54°.

I began work by collecting seeds of the *Primulas*, *Nomocharis* and *Meconopsis*, making long excursions up the various valleys and glens, and along the ridges climbed in June. But also I went along several new routes, including an ascent of the waterfall cliff; the cascade had

no real snow peaks in the neighbourhood, and no glaciers, though there were many large permanent snow beds which had been glaciers not long ago. During these scrambles I gradually collected seeds of all the plants entered in my catalogue as likely, and a few others; *Lonicera*, *Anemone*, *Iris*, *Ilex*, *Cotoneaster*,

FIG. 230.—COOLIES AT BREAKFAST.

and numerous *Rhododendrons*, including several dwarfs. I did not start on the *Rhododendrons*, however, until nearly half-way through October.

There were quite a number of flowers, even as high as 14,000 feet; two fine porcelain-blue *Gentians*, species of *Codonopsis*, *Saussurea*,

as tender are now developing into large specimens in the open garden. So large and well-furnished have many of these become that it will require a very severe frost or a recurrence of such frosts to seriously affect them.

There are many who argue that such a winter as that of 1895-1896 would effectually clear our

ACCLIMATISATION OF PLANTS.

ALTHOUGH the acclimatisation of plants is a subject of great importance to gardeners, science can give us little guidance as to the temperature necessary to maintain life in any plant new to cultivation. Appearances are deceptive; no one by looking at a plant—not even by a close botanical examination—can say whether it will survive 20° or 30° of frost. What is it that enables a plant to withstand severe cold? It would seem that the plant gradually adapts itself to low temperatures—but how? As gardeners, I am afraid that we have been more concerned in simply finding out this quality than in searching for the reason of it.

A notable attempt has been made during the last thirty years to test the hardiness of the many plants introduced of late and others which had hitherto been grown only under glass. This has been an easier task than formerly because propagation is now better understood, and more practised in private gardens, and surplus plants are available for experimental treatment. Since the war, great strides have been made and many plants once regarded

gardens of plants which, admittedly unique and beautiful, are regarded as unreliable. Granted that a hard winter would cause severe losses, the fact remains that such frosts occur only at extremely long intervals, and that many of these plants—*Abutilon vitifolium*, for instance—grow and come to maturity quickly, repaying in a short time any care bestowed upon them.

Some old greenhouse plants (*Trachelospermum jasminoides* and *Abutilon vexillarium* may be cited as examples) were rarely presentable under glass, but may now be seen flourishing on many outside walls in the southern counties. Again, there are many plants, to which, even in large houses, it is difficult to allot sufficient space. Camellias, for instance, are nearly always cramped for room, and, as specimens, are not comparable to those grown under favourable conditions outside. This phase of gardening then, although it carries a certain amount of risk and some drawbacks, holds out a rich reward to those, who, making stepping stones of their failures, go on undaunted.

The last decade has been a favourable one; there has been no winter to equal that of 1916-1917 in severity; the low temperature and bitter east winds experienced for so many weeks at that time, severely tested plants from Australia, New Zealand, South America and China. Owing to the war, and consequent shortage of labour, it was impossible to afford them much protection, or to do more than record the killed and injured under headings that often needed further qualification.

Tabulated records are often most contradictory. Thus, in a report carefully prepared by Mr. E. A. Bowles, and issued by the Royal Horticultural Society, one finds that plants of *Abutilon vexillarium*, grown against a wall at Monreith, were killed and cut down to the ground level respectively, while others in the open were uninjured. In most other gardens a wall proved a safeguard. *Gaya Lyalli*, now registered as fairly hardy, was cut to the ground at Guildford, and badly injured at Exeter, whereas at Aldenham, Enfield and Kew, it escaped injury. The Chinese plants, principally from the north-west, introduced by the French missionaries, but more especially by Dr. A. Henry and Mr. E. H. Wilson, withstood the test remarkably well. This fact, no doubt, led to further exploitation of that region and increased care in collecting seeds under conditions that would secure the hardiness of the plants raised.

In the late Andean expedition, seeds of some well-known plants were collected from new and cooler districts with that object in view. My thirty years' experience in acclimatising plants in these gardens leads me to attach particular importance to this point. In many cases, notably with *Eucalyptus cordata*, now thirty or forty feet in height, success was only attained after five or six plants had failed. A similar experience might be recorded of Tea plants, until a dwarf, shrubby kind was found, probably imported from a high altitude, which has not only lived but flourished.

Site, exposure, drainage, soil and the condition of the plant, all vary its ability to withstand frost. Even in favoured counties, sites a few hundred feet above the average level would appear advantageous; the cold air sinks and the higher ground escapes the destructive frosts that are the bane of low, sheltered valleys.

Those parts of Great Britain which are most favourable to the growth of tender plants are usually near the sea; undoubtedly the climate is milder; it is, however, open to question whether this alone is the reason why so many plants succeed in such localities. Exposure to the sun and air, and the increase of light by reflection from the sea, all play an important part in maturing the woody stems of many half-hardy plants. This is well shown at Highdown, where Major Stern contends so successfully with difficulties of subsoil, etc. The value of exposure for numbers of plants, especially those from New Zealand, is exemplified at Wakehurst Place, where species usually over-sheltered, are growing in beds extended into the open park. The sturdy, short-jointed growth obtained is not only more floriferous, but hardier. At Nymans,

the gardens are about 450 feet above sea-level, and, but for trees, are exposed to wind from every quarter except the north-west, and though sometimes a cause of loss, we regard the site as beneficial, on the whole.

All gardeners—and many garden owners—know how difficult it becomes, in an already crowded garden, to choose suitable stations for plants. So long as new ground is being taken in little trouble is experienced. There comes a time, however, when extension is no longer possible, yet new plants are continually arriving, and places must be provided for them. It is then that sun-loving plants are often placed between taller specimens, and are cut off from air and sunlight, except for a short period of the day. Plants so placed may, in the event of destruction by frost, be recorded as killed or injured but they provide no evidence of the hardiness of a species. The differences which make for success or failure are very slight. A position on a dry bank where a plant grows slowly and matures thoroughly will sometimes prove successful for plants that have hitherto failed completely.

Shelter from the north and east may take many forms, such as hills, woods, belts of trees, hedges, walls and evergreen shrubs. The piercing winds from those points during prolonged frosts are much to be dreaded; they dry out the sap from evergreens when there is little chance of it being replaced. It seems almost a paradox to state that the lower half of an exposed north wall is a sheltered place, but it is so in practice, especially if there is protection on the east; probably air currents form a curve before reaching the wall in order to surmount it.

Soil greatly influences the hardiness or otherwise of plants; in rich soils the growth is so gross that it is with difficulty ripened before the advent of winter. Very dry soils, too, have a distinct disadvantage in that growth is often checked by drought and commences again in late summer or autumn, only to be destroyed by frost. A soil of medium quality, containing a fair quantity of grit or stone would appear ideal.

The condition of the plant is of great importance; the need for inherited hardiness has already been stressed, but the individual plant should also have a good start in life. It should not be subjected to undue heat in propagation, but grown hardily from the first, and acclimatised so much as possible. Early planting, say, in March or April, will allow it time to become established before winter. To meet competition, the nurseryman is often obliged to grow plants thickly together and sell them when they are rather small and weak. If dwarf enough they may be grown on in frames. Taller examples are more difficult to deal with. Too often they are housed in late fruit houses, which need to be kept warmer just when the plants should be receiving free ventilation.

The question of protection has caused much controversy and gardeners are about equally divided concerning its advantages and disadvantages. There are times when protection is very useful, especially to young plants, and it is astonishing what a small amount is sometimes sufficient to save life. This was forcibly brought to my notice many years ago, when mourning a plant of *Rhododendron indicum*, apparently totally destroyed. A Musa leaf had been dropped on a part of the plant, pressing it to the ground, and the portion thus protected escaped injury.

Those who should be experienced in this matter tell us to use dry covering only, and that if it is wet it is worse than useless. There is little doubt that a dry covering is most effectual; but frosts usually last for a few days and sometimes weeks. If there is the slightest sleet or thaw, the coverings will become wet, and in how many large gardens is it possible to remove and dry them?

In the years before the war we protected a considerable number of large plants, and the operation rarely occupied less than three or four days of steady work. The method which proved to be most effectual was to cover the roots heavily with leaves or Bracken, and secure mats or evergreen boughs at a distance of about eighteen inches from the plant, either by making a wigwam over it or, in the case of wall plants,

by leaning poles against the walls and covering them. In every case a space between plant and covering should always be secured. In the future it may be possible to decide by examination the hardiness of a plant, and not only to foretell frost, but also its severity and duration sometime before hand; when that day arrives gardening will have advanced one step nearer to becoming an exact science. J. Comber, Nymans Gardens, Handcross, Haywards Heath.

NOTICES OF BOOKS.

Gardens Old and New.

THE publishers of that excellent Berlin gardening journal, *Gartenschönheit*, have a pleasant habit of getting people to write discursively about something which interests them enormously—such, for instance, as the planning of their own garden in a setting of glorious mountain and river scenery—and get together a number of photographs to illustrate their exuberant outpourings. Of this most promising material the publishers make books, squarish and flat, printed in generous Latin type (no crabbed Gothic for them) on good, clean, white art paper, for the delectation of all who love gardens and garden making, and can read German. In *Saaleck** we have a fascinating story of the making of a garden and a house—this order we feel sure the author would consider correct—from the nucleus of an older one, in the lovely Saalfeld district of Germany, overlooking the Saale River. Every nook and corner of the estate, every wide-flung river and mountain and forest view is pictured to arouse the envy of the reader. Or, his emulation, if his means will allow it. But this garden-making business is an expensive one, contrive how one will.

In the second of the books before us,† the theme is still garden-making, but this time we are taken back to the seventeenth and eighteenth centuries, and even earlier, and shown the gardens made in and around Danzig, all those years ago. If one asks, why particularly Danzig? the answer is that the publishers are wise enough to know that if they have found someone—in this case, Herr Hans Reichow—who is tremendously interested in ancient garden-craft in Danzig, he will know how to make his readers interested too. Moreover, gardening went in fashions then, as it does now, and the gardens pictured in this volume resemble surprisingly the English gardens of the same periods—possibly designed, in part at least, by the same landscape gardeners, people like Le Nôtre, who went from place to place, shedding little Versailles and Marlys all over Europe. This is the sort of book to take on a railway journey, or with which to make the most of a snatched half-hour in an easy chair in front of a good fire.

Flowers in the Home.

BROADLY, there are three methods of arranging flowers for home enjoyment. These may be termed the specimen flower, the natural, and the display. A single bloom, or a spray, placed in a suitable vase gives pleasure to the real lover of flowers, while others prefer their flowers to be arranged as naturally as possible, either with their own or some other foliage which could appropriately be associated with the growing plant. The display style is frankly artificial in its conception and, provided harmony is attained, different flowers and any foliage may be used.

With these general principles the writer of *Flowers in the Home*‡ seems to be thoroughly conversant, but, unfortunately, the illustrations are not happy examples of the infinite possibilities of the floral decorator's art. In the frontispiece of white Tulips the flowers are

**Saaleck*. Von Paul Schultze-Naumburg. Verlag der Gartenschönheit, Berlin Westend. Paper M.4, linen M.6.

†*Alte Bürgerliche Gartenkunst*. Von Hans Reichow. Verlag der Gartenschönheit, Berlin Westend. Paper M.4, linen M.6.

‡*Flowers in the House*, by Irene Watt. Published by A. and C. Black, Soho Square, London. 2s. 6d. net.

almost lost in the light background. The bowl of Coltsfoot gives no suggestion of the peculiar charm of these early spring, wild flowers which would not thrive amidst dominant foliage and, unless arranged naturally, one feels they should have no place on a polished table. The sparse vase of "Statice latifolia and spent Spiraea" would appeal to very few and the sprawling sprays of Holly are far from being characteristic of our most cheerful native evergreen.

But one appreciates the difficulties of illustrating a book of the character of that under review. Most of us who have been responsible for floral decorations of any pretensions have regretted that what we, at any rate, have considered our most successful attempts, could not be photographed. So that, unless such a book were long anticipated, the writer could rarely depict her own work. Mrs. Irene Watt has written a very pleasant little book—perhaps all the more agreeable reading because it is discursive—which, while describing many attempts also contains suggestions for decorations for various occasions and positions. The advertisement of the book states that the proceeds go to the Edinburgh University Settlement. A. C. B.

MESEMBRYANTHEMUM.

(Continued from page 471).

12.—GLOTTIPHYLLUM, HAW.

FIG. 231.—GLOTTIPHYLLUM ERECTUM.

Apical part of three leaves, and base of a leaf showing the pustule, all from one plant; natural size. Flowers pedicellate.

17. *G. erectum*, N. E. Br. (Fig. 231, and p. 291, Fig. 132).—Stems elongating, decumbent or prostrate, and up to 8 inches long, 4 lines thick, sparingly branched with 2–3 pairs of leaves at the end of each branch. Leaves usually in 2 ranks, but sometimes the pairs obliquely cross one another, distinctly erect or ascending, $2\frac{1}{2}$ –5 inches long, $\frac{1}{2}$ –1 inch broad and 3–5 lines thick, these variations even on the same plant at the same time, strap-shaped, with parallel sides for $\frac{2}{3}$ of their length, then tapering to an acute or obtuse apex, which is apiculate, at least when young, flat or slightly convex on the face, convex on the back, not keeled, and all similar at the tips, soft and pulpy; surface smooth, glabrous, deep grass-green. Pedicel $1\frac{1}{2}$ inch long, $1\frac{1}{2}$ line thick, erect, terete, glabrous, green. Calyx subequally 4-lobed, green, triangular and about 5 lines in diameter when in mature bud, the outer lobes 6–7 lines long, 3 lines broad, ovate-lanceolate, acute, and

acutely keeled down the back. Corolla 2–2 $\frac{1}{2}$ inches in diameter, expanding in the morning in full sunshine only, closing about 3 p.m.; petals 40–45, in 2–3 series, slightly ascending, spreading (not horizontally spreading), 12–13 lines long, $\frac{1}{2}$ –1 line broad, linear, obtusely pointed at the apex, entire, bright clear yellow on both sides, but scarcely or slightly shining. Stamens very numerous, erect, 3–3 $\frac{1}{2}$ lines long; filaments not bearded, yellow; anthers light

FIG. 232.—GLOTTIPHYLLUM GRANDIFLORUM.

Leaves and pustule, natural size, except as to length; adapted from Salm Dyck. Flowers sessile.

orange-yellow. Stigmas 8, ascending, $\frac{1}{2}$ line long, plumose, yellow.

Victoria East Division: Near Alice, Leslie. This is the plant which, in *The Gardeners' Chronicle*, 1921, Vol. LXX, p. 327, Fig. 146 I thought might be *G. pustulatum*, but now that I have obtained from Dr. Muir

FIG. 233.—GLOTTIPHYLLUM MUIRII.

Apical halves of three leaves, natural size; all from one plant. Flowers sessile.

the true *G. pustulatum* from Uitenhage Division I find to be quite distinct and well characterised by the constantly erect or ascending and acute (not obtuse) leaves. A living plant with fruit upon it, from which I raised several plants, was sent to me several years ago by Mr. T. N. Leslie. Fig. 231 shows

the character of the apex of the leaves, by which it may be distinguished from *G. pustulatum*, and also the pustule.

18. *G. grandiflorum*, N. E. Br., in *The Gardeners' Chronicle*, 1921, Vol. LXX, p. 327 (Fig. 232).—Growths prostrate. Leaves in two ranks, slightly sloping downwards and adpressed edgewise to the ground, 3–4 inches long and an inch or rather more in breadth, strap-shaped, flat on the face, with a large pustule at the base, convex on the back, obtuse and slightly hooked or upturned edgewise at the apex, and the larger of each pair with an oblique keel on the face near the apex, very fleshy, pale green. Flower sessile. Calyx 4-lobed, with ovate lobes apparently about as broad as long. Corolla 3–4 inches in diameter, scarcely scented; petals in two series, cuneately linear, obtuse and minutely toothed at the apex.

Mesembryanthemum grandiflorum, Haw., in *Phil. Mag*, 1826, Vol. LXVIII, p. 327; Salm Dyck, *Mes.*, §8, f. 3. *M. linguiforme* var. *grandiflorum*, Berger, *Mes. und Port.*, p. 242.

South Africa: Locality unknown; introduced by Bowie in or before 1826.

This fine species appears to have died out of cultivation and has not been rediscovered. I have never seen it. Fig. 232 is adapted from Salm Dyck's figure quoted above.

19. *G. Muirii*, N. E. Br. (Fig. 233).—Growths bent towards the ground. Leaves spreading, more or less sloping downwards, in two ranks, usually 3–4 $\frac{1}{2}$ (but occasionally up to 6) inches long, 10–15 lines broad and 6–7

FIG. 234.—GLOTTIPHYLLUM CARNOSUM.

Apical part of leaves from one plant; natural size. Flowers sessile.

lines thick at the middle, straight or but slightly curved edgewise, strap-shaped, with parallel sides, but with the tips of both leaves of a pair upcurved-hooked edgewise, and the hook obliquely-truncate or irregularly shaped and obtuse or very acute, flat or faintly convex on the face, and the face of the larger leaf with an impression of the opposed leaf upon it, forming a ridge along the margin at the middle part and an obliquely transverse ridge below the apex, convex and not keeled on the back; surface smooth, but under a strong lens seen to be covered with transversely-elongated, raised surface-cells, deep grass green. Flower sessile. Calyx triangular and about 6–7 lines in diameter

in bud, 4-lobed, lobes 4-7 lines long, 3-4 lines broad, 3 of them keeled and 2 distinctly ciliate on the keels, the inner with broad membranous margins. Corolla opening in the morning in dull or sunny weather, 3-3½ inches in diameter, not scented; petals numerous, free or nearly so, in two series, somewhat wavy, as if from crumpling in bud, 16-18 lines long, 1½-2 lines broad, linear, obtuse and usually minutely toothed at the apex, bright clear yellow. Stamens numerous, 7-8 lines long, erect and collected into a central mass, concealing the stigmas, light orange-yellow. Stigmas 8, about 1½ line long, plumose, whitish.

Riversdale Division: In the Klein Karoo, 1,200 feet above sea level. Muir 3876!

This is a very fine and distinct species, quite unlike any other, and I have therefore dedicated it to its discoverer, Dr. J. Muir, who has helped me so vigorously in this work with specimens and information. Dr. Muir writes (June 2, 1926), concerning the two extreme forms that exist in nature of the various species of this genus, as previously noted, that he "had both extreme forms (of *G. Muirii*) and of which the smaller, harder form had remained as such since 1924, has now during the past few weeks undergone a change and become greener and juicier, and are quickly assuming the other form." This and other species Dr. Muir states are popularly called by the Dutch colonists "Skilpadkos," i.e., "tortoise food." The plant from which my sketch (Fig. 233, p. 489) was made, was sent to me as being one of the "smaller and harder" forms.

20. *G. carnosum*, N. E. Br. (Fig. 234, p. 489).—Growths apparently tufted or crowded upon the top of the rootstock, more or less depressed towards the ground. Leaves in two ranks, very spreading, 1½-3 inches long, usually 9-10, but sometimes up to 13 lines broad, 4-7 lines thick, more or less strap-shaped with parallel sides, usually slightly curved edgewise downwards, and one leaf of a pair recurving, sometimes very slightly upcurved edgewise (but not at all hooked) at the apex, one leaf of a pair flat and the other slightly convex on the face, and the larger leaf produced beyond the oblique ridge where the flat face ends and obliquely keeled, very convex on the back, obtusely and often obliquely rounded at the apex, rarely with a minute apiculus; substance thick, soft and pulpy; surface smooth, but with minute, raised, linear, transverse surface-cells as seen under a strong lens, glabrous, grass-green, not pellucid-dotted. Flowers sessile. Calyx 8-9 lines in diameter in mature bud, acutely 3-angled, unequally 4-lobed, with three of the lobes acutely keeled on the back, the two larger 8-9 lines long and about 4 lines broad, ovate, acute. Corolla 3 inches in diameter, cup-shaped, opening in sunshine, slightly scented; petals about 45, in 1-2 series, 1½-1¾ long when fully developed, 1-1½ line broad, linear, with subacute and more or less revolute tips, bright clear yellow, scarcely paler on the back, not shining. Stamens erect, lax, about ½ inch long, entirely light yellow. Stigmas 6-8, radiating, about 2 lines long, plumose, whitish. Capsule when closed, 4½-5 lines in diameter, convex and without ridges at the top, with 6-8 valves and cells, and when expanded 7-8 lines in diameter; valves horizontally spreading; 2½ lines long and 2 lines broad, light brown; expanding keels dark brown, without an awn-like or membranous tip, otherwise the structure is the same as for the genus. Seeds about ½ line in diameter, somewhat angularly subglobose or irregularly ovoid, with a very small nipple, minutely tuberculate, dark brown.

Ladismith Division: Between Plathuis and Touws Berg, 2,000 feet above sea level, growing in open places among loose shingle, Muir 3894!

When Dr. Muir sent a plant of this species to me he commented upon the greyish-green appearance of its leaves, and when received the leaves certainly had a slight greyish-green colour, but the fresh leaves that it has made are grass-green; whether they will become greyish during hot summer weather remains to be seen. *N. E. Brown.*

(To be continued).

IDEAL GARDENS AND PLANT LORE.

THE GARDEN OF THE MADONNA.

THE site shall be a sequestered glade opening out to the south and west, sheltered from Boreas and protected from the east wind by a grove of trees. In their genial shade we will raise a suitable arbour from which it will be possible to see, through a considerable portion of the year, in constant succession, some of the plants which have for ages been devoted to Our Ladye. As the number is great it will be impossible to give all the traditions and legends associated with their names, but as complete a list as possible will be supplied so that each garden may have at least a selection from the Virgin's garland.

Let us take first some of the trees and shrubs which tradition has associated with the Madonna and the Holy Child. Some of these afforded protection against the heat of the sun or the men of evil design who followed them in their flight, while others were honoured because they supplied food and nutriment. As Professor de Gubernatis puts it:—

Pour soustraire son fils aux Sicaire d'Hérode, la vierge le cache sous des plantes et des arbrisseaux que, naturellement, elle bénit.

According to a legend which long survived in Tuscany, it was the Juniper which saved the lives of the Virgin and her child during the flight into Egypt on which account it is peculiarly effective in counteracting magic, exorcising evil spirits and rendering charms powerless. The whereabouts of the fugitives were betrayed by the crackling of the seed vessels of the Broom and other plants, but the Juniper enfolded them in its embrace and secured them from harm. Hence the custom in Italy of hanging branches of this tree in stables and cattle sheds on Christmas Day, just as we hang Holly and Mistletoe in the hall. The plant-lore of the Juniper is consequently very profuse, and is well worth reading up by those interested in our subject.

The graceful Weeping Willow will also find a place here, since this plant did for the Virgin exactly what the Juniper did—bending its branches earthward to hide the mother and her son when in danger. To this must be added the fragrant Rosemary, which in Spain takes the place of the Juniper in legendary lore. Nor must the Hazel be overlooked, since it once afforded shelter to the Virgin when she was overtaken by a storm on her way to visit her cousin Elizabeth. The Arbor Vitæ finds its place here because it is used on December 8 at the Festival of the Conception.

Among the fruit trees which are associated with the name of Mary the Palm must have pride of place. The legend has been frequently repeated. Passing through the desert, the Holy Family came to an oasis and took shelter from the excessive heat under the shade of a Palm tree. Looking up, the Virgin saw the fruit and desired Joseph to procure some for her refreshment. The good man marvelled that she should express such a desire, but at a word from the babe the tree inclined its head and allowed her to eat at her pleasure. When her needs were met the tree still remained in its bent position until released by a word from the Christ child. The Palm is upright in consequence, but the Willow weeps because from its branches was made the scourge employed at the trial of the Saviour. A similar legend attaches to the Cherry to that which is told of the Palm, and we may therefore legitimately plant this tree in our Madonna's Garden.

"Before our Saviour's birth, the Virgin Mary, strongly desiring to refresh herself with some luscious Cherries that were hanging in clusters upon the branch of a tree, asked Joseph to gather some for her. He hesitated, and mockingly said: 'Let the father of thy child present them to thee.' Instantly the branch of the Cherry tree inclined itself to the Virgin's hand, and she plucked from it the refreshing fruit."

On this account the Cherry is dedicated, among other fruits, to the Virgin.

To her use also the Strawberry is set apart, while a species of Bean is, in the Isle of Harris, named after her, the Virgin Mary's Nut. But these more rightly find a place in another part of our garden. Here, however, we must make note, among other fruits, of the Orange and Almond, the Fig, Olive and Pomegranate. Caballero has published a popular Andalusian chant in which the Orange is associated with the Madonna. When she and Joseph were travelling with the infant Jesus they came upon an Orange tree which was under the protection of an eagle. A single fruit for the child was asked for by the mother, and the eagle promptly fell asleep. When one Orange had been picked for the babe a second was culled for Joseph and a third for the mother. Not till then did the eagle recover its sight. The original Spanish is given by de Gubernatis in his valuable *Mythologie des Plantes* (Vol. II, page 267), with an interpretation of the legend, a comparison with the Golden Apples of the Hesperides, and a number of other illustrations of the use of the Orange in the plant lore of the Madonna and her child. The Almond was dedicated to Mary in her rôle of Queen of Heaven. In Christian art one often finds the infant Christ represented as holding the fruit of the Pomegranate in his hand and presenting it to his mother. Either the Pomegranate or some other pomaceous fruit figures in a Roumanian chant which has been preserved by Marianescu in which the infant Christ is represented as lying in his mother's bosom weeping. To calm him she puts two Apples in his hand. These he throws away and one becomes the sun while the other gives origin to the moon. After witnessing this exploit, the Virgin announces him and promises that he shall become the Lord of Heaven.

The Olive is regarded as a fit emblem of the Madonna as the mother of Christ. It is the symbol of peace and he the Prince of Peace. Our list of fruit trees would not be complete if we omitted the Fig. During long centuries there was pointed out near the City of Oua, or Heliopolis, the sacred Fig tree under which the Holy Family rested during the flight into Egypt. Here is a recent allusion:—A little beyond the village of Malaria, to the north-east of Cairo, in a "shady garden of rich shrubs and flowers, with the French flag flying from a restaurant at its entrance, encloses the noted Virgin's Tree, beneath whose shade the Holy Family took shelter, so 'tis said, during their flight into Egypt. It is a huge Sycamore, with gnarled and knotted trunk, some ten feet in diameter, throwing out mighty arms which again branch and spread widely, and bear a luxuriant weight of foliage." (*An Eastern Afterglow*, p. 43). Though very old, it is said to bear fruit every year, for the tree is not the Sycamore or Mock-Plane, but the Fig-Mulberry or Sycamore. Dr. Prior and others have explained the cause of the confusion and traced the legend, with its variants, back to very early times. Some state that the Sycamore opened to receive the fugitives, then closed upon them, opening again after the pursuers had passed. It remained open until the year 1656, when the part of the trunk which had separated itself was broken away. The wood of this tree (*Ficus Sycamorus*) is very durable, and has long been employed by the Egyptians for coffin making and other purposes.

We turn from these trees and shrubs to seek suitable plants with which to construct an arbour. Every reader will recall in the first place the Clematis or Virgin's Bower. It is true that Gerard employed the term on account of its shady growth, and that the name may have been used at one time out of compliment to Queen Elizabeth, but every one now thinks of it as the plant which formed the bower of the Madonna. Fortunately, we have to-day many lovely forms of Clematis, and shall therefore find no difficulty in selecting such as will best serve our purpose. There is another native plant, however which will be useful for trailing over our rustic arbour, viz., the Black Bryony (*Tamus communis*), which bears the English name of Our Lady's Seal. This term, as well as Lady's Signet, is also applied to the plant usually known as Solomon's Seal. Dr. Prior (*Popular Names of British Plants*, page 132) goes into the history

of these names, and supplies a score of others, to some of which allusion will be made later. We shall naturally utilise the Rose either for bower, arbour or pergola. "As an emblem of love and beauty (says Folkard, in his *Plant Lore, Legends and Lyrics*, page 518), the Queen of Flowers was specially dedicated by the Romish

the Weeping Willow will serve us for shelter when we wish to change our position, while the various fruit trees—Apple and Orange, Fig and Pomegranate, Olive, Date Palm and Cherry—will supply us at one season or another with all we may require for refreshment while we lay our plans for the ordering of the beds which will yet be needed for the many plants devoted to the Madonna. *Hilderic Friend.*

(To be continued.)

MARKET FRUIT GARDEN.

THERE was a return to wet weather conditions during November, the rainfall (3.50 inches) being considerably over the average for that month. However, this did not cause much

FIG. 235.—ANTHOCORIS SP. ON UNDER SURFACE OF APPLE LEAF.

Church to the Virgin Mary. She is the Rose of Sharon, the Mystic Rosa (*Rosa mystica*), as well as the Lily of the Valley. In old Italian paintings of the Madonna a plantation garden, or hedge of Roses, is often introduced, enclosing

DAMAGE BY FROST OR PESTS?

A SHORT time ago, Mr. Ware, of Wye College, published an article dealing with damage by frost to fruit trees, in which he showed photographs of leaves exhibiting extensive crinkled areas.

Whilst inspecting some small Apple trees this season—varieties Emperor Alexander and Lord Derby—the writer observed similar effects upon the foliage to that described by Mr. Ware. The fruits, however, displayed no familiar signs of frost damage. On a close examination of the undersides of the foliage a small insect was observed embedded in the tiny cracks or fissures made by the crinkling of the leaf surface. Specimens were submitted to Mr. F. Laing, of the British Museum, who identified them as nymphs of a species of *Anthocoris*, belonging to the Hemiptera.

The species of this genus are predaceous; they play some part in the control of various insects found on plants, including aphides.

It would be interesting to know:—(1) If the damage to the leaves was caused by the nymphs; (2) or if the frost was responsible for damage, and the nymphs found the fissures a suitable place in which to pupate; or (3) if the damage was the result of aphid attack and the nymphs were there because of their predaceous habits.

About twenty-five to thirty per cent of the leaves were affected on Emperor Alexander

FIG. 237.—ANTHOCORIS SP. ON UPPER SURFACE OF APPLE LEAF.

interruption to work. The packing staff, having dealt with all the Apples except those that have been put into store, turned to pruning, which is always their winter job. The other hands were engaged in hoeing or scraping

FIG. 236.—ANTHOCORIS SP., PREDACEOUS ON APHIDES.

the principal figure." Later, we shall find that one or other of the Honeysuckles also find a place here.

Here, then, in our Virgin's Bower for the nonce we may rest. Around us flourish fragrant plants, such as the Rosemary and Juniper;

and about ten per cent. in the case of Lord Derby.

The accompanying illustrations (Figs. 235, 236, and 237) show the type of damage, and photomicrographs of the nymphs in situ. *Theodore Parker,*

the weeds out of the rows of bush fruits, in preparation for the application of manure. The weeds now lie between the rows, and will probably remain there until early spring, when I hope there may be a spell of weather dry enough to enable me to kill some of them by means of

horse cultivation before it becomes necessary to plough a little soil up to the bushes to cover the manure. If there is no opportunity to kill the weeds, then ploughing will have to be managed without it, and plenty of cultivation and hoeing done afterwards. Digging the weeds in between the rows would, no doubt, make the best job of it. This is the method followed with great success by small growers, but it would be a long and expensive business on a large scale. I shall have to do this in the case of some small plantations of Black Currants, where the bushes have grown too large to allow of ploughing. The problem of cleaning bush fruit quarters is, of course, unusually difficult this season, because there was no chance to deal with weeds during the early autumn—in fact, they have hardly been checked since the dry weather in May.

MANURING BUSH FRUITS.

I believe I have enough farmyard manure to dress all my bush fruits this winter. A neighbouring dairy farmer delivered it at intervals during the summer with a motor-lorry; and there are two large heaps in excellent condition for spreading. In recent years I have relied too much on substitutes for farmyard manure. Meat and bone-meal, with the addition of sulphate of potash to make a complete manure, answers very well; but I find that the best growth and the heaviest crop always follow the use of farmyard manure. Quite a light dressing of this suffices, if it is supplemented by meat and bone-meal. The superiority of the farmyard manure probably lies chiefly in its mechanical effect on the soil. Bush fruits appreciate it as a rooting medium, particularly in a dry season. For Gooseberries, farmyard manure is particularly desirable. Mine did well for a few years on the substitute mentioned above; but this season they have made very little growth, and will have to be dunged liberally. The meagre growth is rather surprising, as frost robbed them of quite half their crop and they have not been checked by mildew or aphids. I consider, however, that the season has produced less than normal growth in all fruit trees and bushes.

STORED APPLES.

The bulk of my crop of Bramley's Seedling has been stored, as it seems likely that there will be a substantial rise from the present miserable price early in the New Year. So far, they are keeping very well indeed. Some of them are in a fruit store which has been adapted for operation on the air-cooled system. This store was made many years ago by partitioning off one end of an old barn, building inner walls of boarding, and providing a ceiling under the lofty roof. The space between the walls was filled with saw-dust as insulating material to help in maintaining an even temperature. There were several ventilators at the top of the walls, opening to the inside of the barn. I have now had ventilators made at the floor level, through the walls to the open air, and a shaft built up from the middle of the ceiling. When these are opened a draught of air is created. The object is, of course, to reduce the temperature inside the store by opening the ventilators when the temperature is lower in the open than it is inside the store. When the conditions are reversed the ventilators are closed. The draught is supposed to assist further by carrying away the gases which collect about the Apples for a time after they are first placed in the store. It is too early, of course, to form any opinion as to whether this ventilating system has improved the store; but I am rather disappointed to find that the place takes a long time to cool down, and that it never gets as low as the minimum temperature outside. So far there has been no really severe weather, but I opened the ventilators on such frosty nights as we have had, and have not succeeded in reducing the temperature inside below 40°. I can, however, hold it at that, with closed ventilators, during a period of warmer weather. I am told that this is low enough, and that it is not advisable to get it down below what is likely to be maintained, an even temperature being the main thing.

For two or three weeks after the Apples were stored away they evidently heated a good deal, for the thermometer used to rise considerably above the outside temperature when the ventilators were closed. This, no doubt, accounted for the time taken to get the temperature down in the first place. It was certainly a wonder to me to find that it remained 10° above freezing inside the store on a frosty night. It is amusing to think that, when the store was in its original form, I used to be afraid that the Apples might become frozen. In America, air-cooled stores have proved very successful, as have several that have been made in this country in recent years. The system, therefore, is not in doubt. If mine does not answer it will mean simply that my ventilating arrangements are inadequate and need improvement. In other buildings I have Bramley's Seedling in heaps or clamps under straw. These will serve to compare with the fruit in the store.

APPLE ALLINGTON PIPPIN.

Market growers do not make many mistakes in adopting Apples for commercial culture. If they err at all, it is probably in the direction of excessive caution. They were apparently wrong, however, in planting Allington Pippin, though it is difficult to fathom the reason. In my opinion this is a delicious Apple, provided that it is allowed to hang on the tree long enough to acquire its full, almost Pear-like flavour. Moreover, as grown in my conditions, and in many other places as well, it is brightly coloured. Here, then, we have a coloured Apple of good quality, which is what the public are supposed to want. Yet it is a most unsatisfactory Apple to sell, the price always being low and the demand slow. In my local south coast markets it has a very bad name and is hardly wanted at all. In the north it is rather more appreciated; but my experience is that the extra price secured there is scarcely enough to justify the expense of the long journey. I can only conclude that the public do not agree with my estimation of the flavour. It is possibly a trifle too acid for most people.

A retailer tells me that Jonathan is the most popular Apple on sale at the present time. This is exceedingly sweet and rather soft, though no doubt its brilliant red colour is one of its chief attractions. Allington Pippin's low reputation has been earned partly by the mistake made by some growers of putting it on the market long before it has any flavour. Moreover, on some soils it does not colour well. If it is not to become popular, and it is too late to hope for that now, it is a most undesirable variety to have in a market plantation, for it gives a great deal of trouble. No variety takes longer to prune, owing to the forest of laterals made each year; and it is subject to most of the pests and diseases which are found upon Apples. American blight is more often serious on this variety than on any other; and it is one of the most difficult to keep free from scab. It has the virtue of being exceedingly prolific, though in alternate years only; so the enormous bulk of fruit possibly prevents it from being an unprofitable variety.

THINNING OUT PLANTATIONS.

Last winter I grubbed a great many trees in my plantations, chiefly Apples, where they had outgrown the available space and become overcrowded. One always feels reluctant to take this step and sacrifice trees in full bearing; but it has undoubtedly paid. In this sunless season it has been unusually noticeable that Apples coloured well only where fully exposed. On trees against hedges, or where overcrowded the fruit was very slow to colour. Where the grubbing had been done it was quite obvious that the Apples coloured very much better. The extra space was also much appreciated when spraying. Some of my Plums would be all the better for more space, but they are too old to benefit from grubbing now. Where overcrowded, they tend in time to bear only towards the tops, and the lower branches gradually die out. Young men who intend to enter the ranks of market growers would do well to take to heart the object lessons on the evils of overcrowding to be learned in many of the older plantations. *Market Grower.*

FRUIT REGISTER.

APPLE BRABANT BELLEFLEUR.

QUITE recently several varieties of Apples were sent me for determination and amongst them was the above-named variety. This excellent culinary Apple is of such great merit that one wonders why so many fine old sorts are not in greater demand. Many of them are equal, or even superior, to newer varieties. Several orchards in the Bromyard district contain well-grown trees of Brabant Bellefleur and the fruits command as ready a sale as the best specimens of Newton Wonder.

The fruits are large, three to four inches wide, and three to four inches high, roundish-ovate, inclining to oblong or conical, ribbed on the sides and narrowing towards the eye. The skin is greenish-yellow but changes to lemon-yellow as it attains maturity, when it is striped with rich crimson on the sunny side. The eye is large and open, set in a wide and angular basin. The stalk is short, inserted in a deep russety cavity. The flesh of this Apple is yellow to white, firm, crisp and juicy, with a sugary, aromatic and pleasantly sub-acid flavour. Brabant Bellefleur continues good until the end of April. The variety is also known as Glory of Flanders, but is quite distinct from Flanders Pippin—an Apple grown largely in Berkshire orchards. *Pomona.*

PEAR PRESIDENT BARABE.

HAVING grown this Pear for many years, I unhesitatingly accord it a high position amongst late varieties. Its one fault is a tendency to produce rather weakly growths.

The fruits are of medium size and dull greenish-yellow colour; the flesh is melting, sweet and exquisitely flavoured. President Barabe ripens in February and March. The tree is best accommodated against a south wall and succeeds in cordon form.

Although introduced to cultivation so long ago as 1877—it was raised at Rouen, France—President Barabe is infrequently grown, and would, if better known, receive much greater appreciation as a variety for late use. *Ralph E. Arnold.*

VEGETABLE GARDEN.

WINTER CARROTS.

THE Carrot is a very important vegetable and is always in demand but, whereas the supply of mature roots during the winter and spring months presents no difficulties, the supply of young, succulent roots for use as a table delicacy during the winter calls for greater attention.

In favourable localities and under good cultivation, outdoor supplies may meet demands during the early winter months. On a warm, sheltered border, with well-prepared soil, sowings made so late as September provide small but serviceable roots well into the New Year in normal seasons, but growth becomes stunted after this period, the young roots lose their delicacy of flavour, and it becomes necessary to resort to frame culture for dependable supplies.

For this purpose, well-prepared hot-beds should be made up at intervals from December onwards to ensure successional supplies until early outdoor crops are again available. The most satisfactory hot-beds consist of stable manure and leaves in about equal proportions; this material, when well mixed and thoroughly compacted, gives a steady heat over a considerable period, conditions which suit the growth of the young Carrots admirably. If stable manure is not procurable, leaves alone, or leaves mixed with green garden refuse, make quite good hot-beds and give equally good results. Under these conditions growth is quick and there is no doubt that it is aided by the increased amount of carbonic acid gas resulting from the decomposing hot-bed material, as well as from the heat generated. *W. A.*

THE GLOBE ARTICHOKE.

THE immature flower heads of the Globe Artichoke are much esteemed as a vegetable and certain portions, when bottled, form a useful addition to the winter menu.

It is essential that the soil for this vegetable should be light and well-drained; a thorough preparation of the site should be undertaken during the winter, trenching the ground and adding a liberal quantity of well-rotted manure. A heavy soil may be improved by the use of liberal quantities of road grit, or of light, sandy soil. Planting may be undertaken in March or April, and it is an excellent plan to place groups of these plants in rows three or four feet asunder, allowing about three feet from group to group; a mulching of manure will prevent undue evaporation and, during dry weather copious supplies of water will be needed. In October or November a good mulching of dry straw or other suitable protective material should be applied, but removed in spring, when the ground should be lightly forked and receive a light dressing of rotted manure.

Propagation may be effected by seeds or suckers, the former sown under glass in early spring, and the latter detached from the parent plants so soon as they have made a fair amount of growth in April or May. Seeds cannot be recommended as a means of raising stock, as a large percentage of the seedlings will prove useless; suckers should be procured from carefully selected varieties.

Given reasonable attention, a planting of this vegetable will give excellent produce for several years, provided a warm, sunny position is chosen for them.

The Green and Purple varieties will meet all ordinary requirements, and the former will usually command most favour. *E. A.*

HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

Pea, Amateur's Pride.—Mr. James Findlay's note on p. 473 of *The Gardeners' Chronicle*, regarding Pea Amateurs' Pride, made most interesting reading; but it occurred to me that Mr. Findlay would have had a great disappointment if after his elaborate preparations in digging a trench two feet wide and two-and-a-half feet deep, and giving such a generous supply of manure, he did not get a bumper crop. I doubt if there are many amateurs or private gardeners who would consider a Pea required such generous treatment. If Mr. Findlay will try the variety in ordinary good garden soil, I shall be very interested to know the result. *Donald Allan.*

Schizostylis coccinea.—We were interested in the letter from Mr. Frederick Gooch which appeared in your issue of November 26, p. 431. From what Mr. Gooch states, it would appear that he experiences difficulty in growing *Schizostylis coccinea* owing to his ground being damp. This is interesting and quite contrary to our own experience, which is that this *Schizostylis* may be treated practically as a bog plant. We grow both *Schizostylis coccinea* and the pink variety, Mrs. Hegarty, in our Cornish nursery, in a meadow which lies in a valley and receives all the drainings from the hill above, and is bordered on one side by a stream. The soil is light, but of a black, boggy nature; it never dries out, and in the winter and during wet periods is frequently almost a marsh. The *Schizostylis* flourishes like a weed therein. At our Taplow nurseries, we always try to select a site slightly shaded, and plant the *Schizostylis* in a stiff soil, and in as damp a situation as we can find. Our experience, therefore, is that the *Schizostylis* is quite a moisture-loving plant, and we should have thought the condition Mr. Gooch writes of would have been quite ideal. We can confirm his experience of growing *Schizostylis* in pots, which we find most satisfactory. We have also found that buds picked

from the open, even so late as the present time, may be well opened under glass with charming results. *Barr and Sons.*

Outdoor Oranges.—During the last week in November, I and our gardener gathered two hundred ripe Bitter Oranges and a few Citrons from our outdoor bushes. These fruits will be converted into marmalade and candied peel. Our bushes rarely have any shelter and then only against severe gales and the hailstorms which mark the fruit. I thought your readers might care to know what can be done in west Somerset. *G. Blathwayt, West Porlock House.*

Raising New Hydrangeas.—The article on "Raising New Varieties of Hydrangeas," by Mons. Cayeux, in your issue of December 3, is extremely interesting. The atmospheric conditions at Le Havre are naturally drier than in the British Isles, as I have noted here a tendency to mildew and damping unless the plants carrying seed pods are kept in an airy and dry position. For several seasons past I have seen various plants of *Hydrangea Hortensis* carrying many seed-pods as the result of self-fertilisation, and I often wonder why the idea of raising Hydrangeas from seeds was not thought of earlier. Varieties are becoming so numerous that we may yet have a National Hydrangea Society! *Geo. W. Stacey, Cedars Gardens, Chorleywood.*

Culinary Peas and Superphosphate.—Concerning Mr. Copley's reply re superphosphate and Peas, my warning was based on personal experience, not only on Peas alone but other seeds as well. I have even seen Potato sets rot when superphosphate was sown broadcast over the drills before the sets were covered in. I use superphosphate in conjunction with sulphate of potash on all indoor and outdoor crops, but am always careful not to allow the manure to come into direct contact with seeds or plants. There are several grades of superphosphate on the market, and possibly Mr. Copley's sample was a low grade one and not so potent. I thought a warning might save others from disappointment. Perhaps his seeds were so far apart that they did not come into direct contact with the manure! His information regarding the thin sowing of Peas is not exactly new to gardeners! *Grigor Roy, Stoke d'Abernon Manor Gardens.*

Hydrangea quercifolia and Gentiana Farreri.—I see that *A. G. F.*, in your issue of November 26 (page 425), states that *Hydrangea quercifolia* normally dies down to the ground every winter. At the Botanic Garden here there is a specimen over three feet high and considerably more in diameter, which has never yet had its sturdy stem cut by the frost. It has been out in the open for fully twenty years, and, having flowered well as usual, is not yet out of bloom (December 6). With reference to the notes on *Gentiana Farreri* in your recent issues I would like to mention that several friends and myself have found this gem easier to grow than *G. sino-ornata*. One plant I have of *G. Farreri* is a three-year-old from a cutting. Last year it had thirty flowers, and this year over seventy. It is growing in full sun, in a mixture—of no very great depth or area—of equal parts of sand and peat, in a moist and calcareous part of my rock garden. With *G. sino-ornata*, however, I have had no such good fortune, although it has been tried in similar and more substantial mixtures in various positions. *G. S. T., Cambridge.*

Bulbinella Hookerii.—I have read Mr. Arnott's description of *Bulbinella Hookerii* (page 422). He mentions two varieties of which I think the scarcer one, with the larger spikes, flowers and height, is the original *Bulbinella Hookerii* of Bentham and Hooker, while the commoner one, of which Mr. Arnott gives the description, is the variety *angustifolia* of Cockayne and Laing. This is smaller altogether than the type and with narrower leaves, broad at the base, deeply concave and never glaucous as in the type, which may have glaucous leaves. The racemes are both shorter and denser. The type and variety are common, I understand, in mountainous districts of the South Island. *Ronald Smith, Greenhead, Gargrave, near Skipton, Yorks.*

SOCIETIES.

ROYAL HORTICULTURAL.

DECEMBER 13.—Cypripediums were the special feature of the last meeting of the year of this Society at Vincent Square, Westminster, on the above date. The special flower was exceedingly well represented as, indeed, were Orchids generally. The groups occupied a considerable proportion of the space allotted to floral exhibits, and they included many splendid plants. Amongst the general floral exhibits were an extensive collection of Chrysanthemums of the type best valued for market purposes, Carnations and hardy trees and shrubs. There were also many interesting exhibits of garden sundries, paintings of flowers and garden scenes.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Mr. Gurney Wilson (Hon. Sec.), Mr. Frederick J. Hanbury, Mr. S. W. Flory, Mr. A. Dye, Mr. Charles H. Curtis, Mr. J. E. Shill, Mr. W. H. Hatcher, Mr. John C. Cowan, Mr. Robert Paterson, Mr. A. McBean, Mr. T. Armstrong, Mr. H. S. Alexander, Mr. Richard G. Thwaites, Mr. Ernest R. Ashton, Mr. J. Wilson Potter, Mr. Fred K. Sander, Mr. C. J. Lucas and Mr. Clive Cookson.

FIRST CLASS CERTIFICATES.

Cypripedium Windrush var. *Memoria* G. F. Moore (*Radiosum* × *Memoria* F. M. Ogilvie var. *The King*).—In this hybrid the central sepal is almost as large as the dorsal sepal, and each is broad and rounded, white, with heavy purple spottings and green base. The petals are very broad, the dorsal half dull purplish-brown, with green, spotted base, and the ventral half yellowish-green, with small purple spots. As seen from the front, the flower is almost circular in outline. Shown by Miss A. B. Moore (gr. Mr. Page), Chardwar, Bourton-on-the-Water.

Cypripedium H. T. Pitt (*Archimedes* × *Beckmani* × *Christopher Grand Duke Nicholas*).—This is of typical Chardwar form, the huge, rounded, dorsal sepal being white, with a central and basal area of green, spotted with purple; petals pale green, marked with purple-brown and widely extended. Lip pale green. Shown by Miss A. B. Moore.

AWARDS OF MERIT.

Cypripedium Westminster (*Chloris* × *Alciades*).—A neat and distinct hybrid in which the lip is very much shorter than usual and the dorsal sepal and petals are broad. The top and sides of the dorsal sepal are white, and the centre and lower part deep rose, with a rich brownish tinting. Petals and lip brown, with honey-yellow markings. Shown by Messrs. BLACK AND FLOREY.

Laelio-Cattleya Hilary var. *Majestica* (L.-C. *Soulangae* × *C. Fabia*).—A bold and handsome variety of clear, deep rose-purple colouring, with a ruby-purple lip edged with mauve and lined in the throat with gold. Shown by Messrs. COWAN AND CO.

Odontonia Olga (*Odontonia Thisbe* × *Odontoglossum crispum*, Premier type).—A chaste flower, with pure white sepals and petals, the latter lightly fringed. The white, red-marked lip is like an enlarged and flattened *O. crispum* lip. Shown by Messrs. CHARLESWORTH AND CO.

GROUPS.

A marvellously fine group of superb *Cypripediums*, all grown splendidly, was shown by Miss A. B. Moore (gr. Mr. Page), Chardwar, Bourton-on-the-Water. The Chardwar hybrids are famous, and this was a magnificent presentation of them. For colour, size and form probably no finer collection has ever been exhibited. A few of the largest hybrids shown were *C. Chardwar* in variety, *C. Gwen Hammer*, *C. Chrysostom* var. *Amy Moore*, *C. H. T. Pitt* and *C. Memoria* H. J. Elwes. Some of the richer-coloured sorts were *C. Memoria* F. M. Ogilvie var. *The Queen*, purple, white, green, brown and honey yellow; *C. Cappa Magna*

var. Fred Sander, C. Mecca (Cardinal Mercier × Price Albert var. Mecca), with finely-spotted dorsal sepal, and a band of honey-yellow around the brown petals; C. Monialis, C. Perseus and C. Prince Albert, Chardwar var. Other fine things were C. Boltonii represented by about half-a-dozen freely-flowered plants; C. Mildred, C. Seckon var. Gold Mohur, C. Bordubi var. Eau de Nil, wholly soft, greenish-yellow; C. Sir Trevor var. virginata, and C. The Prince.

A large group was arranged by Messrs. H. ALEXANDER, LTD., who used *Oncidium varicosum* Rogersii and *Vanda coerulea* among their *Cypripediums*. These last were well shown and included large and excellent plants of C. Ballet Girl, C. Roundhead, C. Corsair, Holford's var., C. Minotaur, C. Golden Fleece, Westonbirt var., C. Latona and C. Garibaldi. *Coelogyne Mooreana* was well represented, as also were *Laelio-Cattleya* Golden Beauty, of lovely colour, *Cypripedium* Boltoni, C. Actaeus Bianca, C. Nesta and C. Ilona, the last of pleasing soft yellow colour.

Mr. J. EVANS, Colwyn Bay, showed a very pleasing group of well-grown Orchids wherein *Vanda coerulea* was used as a background for *Calanthe Harrissii*, *Odontoglossum crispum*, *O. eximium*, *Brasso-Cattleya* British Queen, *Cypripedium insigne* Sanderæ, finely grown, C. Alcimeda, C. Alcibiades, C. Forest King and many other excellent Orchids.

Many interesting plants figured in the group shown by Sir JEREMIAH COLMAN, Bart. (gr. Mr. J. Collier), Gatton Park, Reigate. There were big plants of *Cypripedium* King Emperor and C. Elatior, capital examples of *Sophrontitis grandiflora*, *Masdevallia towarensis*, *Sophrone-Laelio-Cattleya* Isabella and *Odontoglossum* Monte Carlo. Species were represented by *Zygopetalum rostratum*, *Cirrhopetalum refractum*, *Masdevallia Parkeri*, *Bulbophyllum fasciatum* and a tiny, unnamed species of *Oberonia*.

E. R. ASHTON, Esq., Broadlands, Camden Park, Tonbridge, showed several plants of *Oncidium cheiroporum*, all beautifully flowered, one carrying eleven spikes; *Sophrone-Cattleya* Sir Mervyn Buller, *Odontonia brugensis* var. Distinction, *Masdevallia towarensis*, freely-flowered (Cultural Certificate), and the beautiful, yellow *Brasso-Cattleya* The Baroness.

Cypripediums were extensively displayed by Messrs. COWAN AND CO. against a background of *Odontoglossums* and *Laelio-Cattleyas*. A few outstanding *Cypripediums* were C. *Regulus*, C. Corsair, Holford's var., the dark-hued C. Perseus, C. Fantasia, C. Royal George, C. Niobe-Leeanum, very pretty; C. Golden Wren and C. Cyril Lea.

Messrs. SANDERS' exhibit included a fine example of *Cymbidium* Edward Marshall, with a spike of eighteen big flowers; *Laelio-Cattleya* Yukon var. Golddigger, of lovely yellow, orange and brown colour; *Vanda coerulea*, *Oncidium Mantinii*—a showy natural hybrid, with golden and greenish-brown flowers; *Cypripediums* in great variety, *Masdevallia towarensis*, *Coelogyne Rhodeana*, *Lycaste Imshootiana* var. *bellissima*, *Odontoglossum cordatum* and *Laelia Gouldiana*.

The *Cypripediums* from Messrs. J. CYPHER AND SONS were well-grown and included capital examples of C. Golden Queen, a very attractive Orchid; C. Thompsonii, a richly-coloured seedling from C. Piccanniny, C. Prince Albert, C. Corsair, C. Miriam, C. Alabaster, C. Lord Wolmer, C. Ballet Girl and C. Elatior, *Shrubbery* var., with deep, purple-brown colouring and a bluish-white, heavily-spotted dorsal sepal.

Messrs. CHARLESWORTH AND CO. submitted a group in which Orchids of great variety were shown. *Odontoglossums* were well represented by *O. crispum*, *O. e. xanthotes*, *O. Ophelia*, *O. Amethyst* and *O. Wilkeanum aureum*, and *Odontodas* by *O. Acis* and *O. Marjorie*. *Miltonia* Freya and M. Venus, *Cypripedium* Thalia and C. Maudiae magnificum, *Masdevallia towarensis*, and *Sophrone-Laelio-Cattleya* Flamingo were also shown by this firm.

Cypripediums were also displayed by Messrs. ARMSTRONG AND BROWN, each plant standing free of its neighbour, C. Maudiae, C. Roger Sander, C. T. B. Armstrong, C. Lucifer, C. Alcibiades illustris, C. Lord Wolmer and C.

Memoria F. M. Ogilvie var. The Premier, were a few outstanding kinds.

The group arranged by Messrs. J. AND A. McBEAN was bright with *Odontodas* and *Odontoglossums*, but included *Cypripediums* and a few other Orchids. *Cattleya* Etina, C. Venus, C. Luegae, *Laelio-Cattleya* Profusion, the richly-coloured L.-C. Linda, *Cymbidium* rosefieldiense and C. Doris made a brave show with the other kinds and varieties displayed.

Miltonia Sanderiana var. Redwing was conspicuous in a group composed chiefly of *Cypripediums*, from Messrs. BLACK AND FLORY. The more notable *Cypripediums* were C. Westminster, C. Golden Wren, C. Atlantis, C. Etta and C. Bisham.

Messrs. STUART LOW AND CO. had a small group that included *Oncidium* Papilio, *Sophrone-Laelio-Cattleya* Flammea with three handsome flowers, *Laelio-Cattleya* Nadina, L.-C. Schröderæ in fine form, the rare *Coelia Bauerii*, *Zygopetalum* Mackayi and *Sophrone-Cattleya* Enid. Messrs. SUTTON BROS. showed a few *Cypripediums*, *Cattleyas* and *Odontoglossums*.

Mr. A. J. KEELING showed a group of *Cypripediums*, his C. Arachne var. Charm, C. Nesta II and C. Anita attracting attention; a flowering plant of *Phaio-cymbidium* chardwarensis was also included.

Floral Committee.

Present: Section A.—Mr. H. B. May (in the chair), Mr. J. F. McLeod, Mr. Arthur Turner, Mr. Charles E. Pearson, Mrs. E. M. Wightman, Mr. William Howe, Mr. J. M. Bridgeford, Mr. E. R. Janes, Mr. R. Findlay, Mr. A. E. Vasey, Mr. W. B. Gingell, Mr. D. B. Crane, Mrs. Helen Lindsay Smith, Mr. G. W. Leak and Mr. W. D. Cartwright (Secretary).

Section B.—Mr. Gerald E. Loder (in the chair), Mr. Charles T. Musgrave, Mr. C. Williams, Mr. W. J. Bean, Mr. G. Reuthe, Mr. George Harrow, Mr. F. G. Preston, Mr. Arthur Bedford, Mr. E. H. Wilding, Mr. Mark Fenwick, Mr. Amos Perry, Mr. W. B. Cranfield, Mr. W. G. Baker, Mr. L. R. Russell and Mr. N. K. Gould (Secretary).

AWARD OF MERIT.

Aspidium (Polystichum) aculeatum var. *angulare flabellipinnatum*.—A well-grown specimen, bearing graceful, dark-green fronds, of this uncommon variety of the soft Shield Fern was shown. We understand that it was collected in Dorset. The variety differs chiefly from the type in its stiffish, fan-shaped pinnae. Shown by W. B. CRANFIELD, Esq., West Lodge, Enfield Chase.

GROUPS.

An extensive collection of *Chrysanthemums* of the best market type was displayed by Mr. A. G. VINTEN. Yellow varieties of rich colouring were very prominent and the chief Japanese varieties were Golden Butterfly, of glowing golden colour; Golden Wonder, Yellow Favourite, Balcombe Beauty and Pioneer; while Golden Seal, amongst the Singles is another valuable yellow variety. Winter Cheer, a valuable late variety of rich rose-pink colour, and Mayfield Sunrise, its rosy-amaranth sport, were exceedingly beautiful sorts, while among other Japanese the Single varieties Mr. J. A. Barrell, rich chestnut, and Balcombe Gem, orange-buff, were greatly admired.

A neat little group, arranged by Messrs. L. R. RUSSELL, LTD., contained various foliage plants, winter-flowering *Begonias*, *Aphelandra tetragona*, *Rhododendron Taylori* and R. Indian Yellow.

Messrs. C. ENGELMANN, LTD., set up an admirable collection of greenhouse Carnations in which the prominent varieties were Topsy, Red Laddie, Hebe, Rouge, Master Michael Stoop and Betty. Messrs. ALLWOOD BROS. staged a few vases of perpetual-flowering varieties, with Oceanic, blush-pink, and Mermion, rich pink with white margins, of the perpetual-Malmaison type, and a good selection of *Dianthus* Allwoodii varieties. The last-named included Pat, rich rosy-cerise; Barbara, ruby-crimson, and Maud, salmon. Mr. J. J. KETTLE had a good collection of Violets. Princess of Wales was the chief variety, and he also had bunches of *Ascania*, a dark blue single

variety with a suggestion of reddish tinge, and Governor Herrick, a single Violet of smoky-blue colour.

A goodly collection of Conifers suitable for the rock garden was arranged by Messrs. W. WOOD AND SONS. These were chiefly species and varieties of *Picea*, *Cupressus* and *Juniperus* with an occasional specimen of *Sciadopitys verticillata*. The bronzy, winter colouring of *Retinospora* (Thuya) ericoides and *Cryptomeria japonica elegans* was very effective. At one end of the group there was a number of little plants of *Skimmia Fortunei* well-furnished with bright berries.

In his exhibit of dwarf Conifers and other hardy evergreens, Mr. F. G. WOOD included a number of miniature gardens and a small collection of alpine. Miss GLADYS HOWES also showed miniature gardens, and the Misses HOPKINS had a small rock garden, suitably planted. Mr. JOHN KLINKERT contributed a collection of topiary specimens in evergreen Box. Many forms and shapes were represented and all were well-grown.

By the Gallery, Messrs. BOULTON AND PAUL erected one of their well-known little green houses, with garden frames. There were also shown an Atco Motor lawn-mower; the useful Shoulder Hoe; the Rolcut Secateurs; the Chase Continuous Cloche; plant tubs by Mr. A. J. CLARKSON; vases and other garden ornaments in stone by Messrs. SANDER AND CO.; stone vases by the EMPIRE STONE CO., LTD.; "Gar-pa" stone paving, in red and grey; Jeyes' insecticides and disinfectants; the Mortegg Winter Wash, by Messrs. MURPHY AND SON, and the Briton-Ferry manures and insecticides.

Fruit Committee.

Present: Mr. Joseph Cheal (in the chair), Mr. H. S. Rivers, Mr. George F. Tinley, Mr. E. A. Laxton, Mr. P. A. Tucker, Mr. E. Neal, Mr. Edwin Beckett, Mr. George E. Woodward, Mr. W. H. Divers, Mr. A. W. Metcalfe, Mr. J. Wilson, and Mr. A. N. Rawes (Secretary).

Mr. A. ALLARDICE, The Gardens, Burwarton Hall, Bridgenorth, sent the Apple Cardross Green (described in *Gard. Chron.*, November 12, p. 392), but the samples were rather mealy and seemed unlikely to justify the claim that they will "keep till June."

Samples of Apple Perkin's A.I. were sent to the Committee by F. BOSTOCK, Esq., Pitsford House, Northampton, for comparison with Lane's Prince Albert. This variety appeared exactly similar, and the general opinion was that the two are synonymous.

Mr. P. C. M. VEITCH sent samples of Cornish Aromatic Apple for comparison with another Apple which the Committee considered identical with it.

HARROGATE HORTICULTURAL.

A CHRYSANTHEMUM show, under the auspices of the Harrogate and District Horticultural Association, was held at the St. Peters School on Saturday, November 26. It was well attended and great interest was shown in the exhibits. The entries were good, both in the professional and amateur classes. The November Chrysanthemum shows used to be a popular feature at Harrogate, and gratitude is felt towards the Horticultural Association for reviving them.

The show was opened by the President, Alderman D. Simpson, J.P., who takes a great interest in the Society and in his remarks he stated that the Corporation was in a difficulty with regard to the Winter Gardens and the larger shows of the North of England Horticultural Society, which had been such a great success during the time they had been held at Harrogate. As a Corporation they desired to give support to any organisation which had for its objects the maintenance of high standards of horticultural and similar work. Whether it would be possible to make Harrogate a centre for functions of a character which were useful not only to the town but to the country as a whole was a question that might be considered.

Mr. A. WHITELOCK was awarded a Large Gold Medal for a fine group, and Large Silver Medals were awarded to Mr. CARDWELL and Mr. R. JONES for their displays.

In several classes there were new varieties

such as Yellow Majestic, Red Majestic, Thalia, Andania and Mrs. A. Holden, but the premier award went to a bloom of Mrs. B. Carpenter in Mr. R. JONES' stand. The principal prize-winners were Mr. R. JONES, Mr. H. LUNN, Mr. C. T. HAWKES, Mr. N. DRING, Mr. J. BELLERBY and Mr. C. F. SPINK. Mrs. BIRKETT and Mrs. BUDD were successful in the decorative classes.

BRITISH CARNATION.

THERE is no doubt that an annual dinner offers a pleasant opportunity for a discussion which the more formal annual meeting does not permit, therefore the double functions of the above Society were held at Frascati's Restaurant on the 29th ult.

In recognition of twenty years' service as Show Superintendent, a presentation wallet of bank notes and an illuminated address and list of subscribers was made to Mr. E. F. Hawes. In making the presentation, Mr. H. T. Mason, the President of the Society, commented on the efficient way Mr. Hawes always managed the exhibitions, while another speaker referred to the fact that he had never known Mr. Hawes to become "rattled" in the face of difficulties—a further test of efficiency.

The guest of the evening was Lt.-Col. F. R. Durham, Secretary of the Royal Horticultural Society, who proposed the toast of the British Carnation Society, and gave a brief outline of the development of the Society's name flower since 1676. He made the important announcement that in future the R.H.S. intended to grant the use of its Hall to kindred societies for their shows, free of charge, a piece of information which was received with enthusiasm, for it was realised that the Council had shown a sympathy with the minor societies which had not been observed previously.

In response, the President, Mr. Mason, made a further announcement of interest, which was to the effect that at future shows the British Carnation Society had decided to take the Border Carnation under its wing, as it was thought that one society was sufficient to represent the Carnation in all its forms.

The Hon. Secretary announced that the Society was never in a better position; its membership is increasing, and two shows will be held next year, one in March and one in July.

IRIS.

THE Annual General Meeting of this Society held at the Grosvenor Hotel, London, on November 30, was preceded by a dinner, in which about thirty members participated.

After the election of several new members, the Hon. Secretary, Mr. G. N. Bunyard, presented the Annual Report, which showed that considerable progress had been made during the year, a large number of new members had been added to the roll, and enthusiasm for the objects of the Society was decidedly increasing. The show organised and held in June last was in every way an unqualified success. During the year, the Society had instituted two Memorial Medals, one in memory of Sir Michael Foster, the other to commemorate the work of Mr. W. R. Dykes. An Iris Society's Medal had also been struck, and the thanks of the Society were due to Mr. Dillistone for preparing the designs for this and the Foster Plaque, and superintending the execution of the dies for these and the Dykes' Medal, which was based on a suggestion made in a drawing submitted by Mrs. W. R. Dykes. The membership of the Society was now more than six times its original foundation, and more members were constantly joining from all parts of the world. The Iris trial garden was now an accomplished fact, and much useful information was being compiled which would be published in due course.

Much as he regretted it, Mr. Bunyard stated that he was compelled, owing to the pressure of business, to relinquish the position of Secretary that he had held since the foundation of the Society. He felt he could do this the more comfortably as the Society's future was assured.

Mr. R. Wallace, in moving the adoption of the Report, said there was not the slightest doubt to whom the success of the Iris Show was

due, and, indeed, to whom much of the success of the Society generally could be attributed, and that was to Mr. Bunyard. He possessed an organising capacity that had proved very valuable, and he was glad that although they were losing Mr. Bunyard as a Secretary, he had consented to be nominated for the Committee, where the Society would still be able to make use of his services.

The Hon. Treasurer reported a cash balance in hand of nearly £50. This, in consideration of the very expensive year, was quite satisfactory, as the cost of the show and medals was heavy. So far as the medal fund was concerned, the subscriptions just about covered the cost of the dies, and the production of medals for this year, and also left a number of medals in hand that would be available for several years. Therefore, the demand on the Society's funds in this respect for the next year or two would be comparatively small. In view of the changes necessary, due to the retirement of Mr. Bunyard, he was relinquishing the position of President and Treasurer, and was gratified that he could hand over to his successor so satisfactory a balance.

Arising out of the report, it was decided to appoint an Hon. Auditor, and in future to publish a balance sheet in the *Bulletin*.

It was also decided that the word "November" should be substituted for "June" in Rule 11, and that the financial year should end on October 31, therefore future annual meetings will take place in November.

The Secretary's and Treasurer's reports were then adopted.

The meeting then proceeded to elect the officers for the year, as follow:—President, Sir Wm. Lawrence, Bt.; Secretary, Mr. G. L. Pilkington; Treasurer, Major George Churcher; Editor, Mr. George Dillistone; Auditor, Mr. L. Caldicott. The vacancies on the Committee were filled by Messrs. G. N. Bunyard and B. R. Long.

After the general business, Mr. George Dillistone opened a discussion on "Iris Nomenclature."

NATIONAL CHRYSANTHEMUM.

ONLY two novelties came before the meeting of this Society's Floral Committee, held at the R.H.S. Hall, on December 12.

FIRST CLASS CERTIFICATES.

Winsome. V.l.a.—A large-flowered Single Chrysanthemum with two rows of broad florets. The colour is deep rose-pink, with a small white zone round the dark yellow eye. Shown by Mr. H. SHOESMITH, Junr., Mayford.

Yellow Star. II.l.c.—A small flower of Japanese type, but produced freely in sprays on long, stiff stems. The colour is pale yellow. This should prove a useful "spray" Chrysanthemum for late market and garden use. In general form, the flowers resemble those of Winter Cheer. Shown by Mr. P. HULSE, Shoreham Place Gardens, Shoreham, Kent.

SALISBURY GARDENERS'.

AT the fortnightly meeting of this Society, held at the White Hart Hotel, on Wednesday, December 7, Mr. S. W. Tucker presided over a large attendance, which included several visitors from the Romsey Gardeners' Society.

The lecturer for the evening was the Rev. D. F. Wright, a delegate from the Romsey Gardeners' Society, who discussed "The Herbaceous Border" in a most delightful manner. There was considerable discussion, and many questions were dealt with. The lecturer was heartily thanked, on the proposition of Mr. A. J. Hooper, seconded by Mr. G. Reid, to which he suitably responded.

Mr. Frampton, Secretary of the Romsey Society, expressed the thanks and pleasure of the visitors, and said he hoped that members of the Salisbury Society would return the visit as inter-society meetings were very valuable as a means of education and social intercourse.

Very fine exhibits of winter-flowering Begonias were staged by Mr. A. J. HOOPER and Mr. H. F. STRONG, for which they were thanked and awarded the Society's Certificate of Merit.

Obituary.

Joseph Biggar.—The death occurred with tragic suddenness on Wednesday, December 7, of Mr. Joseph Biggar who had been associated with the Glasgow fruit trade for over forty years. He had gone on a visit to Edinburgh, and on his arrival he collapsed and died on the station platform. Deceased, who was in the employ of Messrs. McCraig, Gilchrist and Co., was for a number of years resident in America, where he represented several Glasgow firms engaged in the Apple trade, and when Sir Malcolm Campbell began a fruit-farming enterprise in California, some twenty years ago, Mr. Biggar was entrusted with its management.

ANSWERS TO CORRESPONDENTS.

MATERIAL FOR DRIVES.—A. F. Unless you can overcome the prejudice to the use of tar-macadam or tar-slag, we fear you will have difficulty in finding a really suitable material with which to construct a drive capable of carrying heavy motor traffic. Concrete roads covered with a thin layer of rock asphalt are at present in much favour with engineers, but unless the traffic at your establishment is abnormally heavy, concrete would be too expensive for the purpose. We suggest that a drive surfaced with a good thickness of tar-slag would meet your requirements admirably, in so far as wear and tear are concerned. The objection to the colour of this material might be minimised by tar-spraying the surface of the drive after it has become thoroughly consolidated, and then spreading over it a thin layer of red shale or of three-eighths-of-an-inch limestone chippings. If this topping is well rolled into the tar matrix by means of a steam or petrol roller the road will retain the colour of the surfacing material—red in the case of shale, white if Buxton limestone gravel is used.

NAMES OF FRUITS.—X. Y. Z. Pear, decayed; 1, Shepherd's Fame; 2, Cox's Pomona; 3, Beauty of Waltham; 4, King of the Pippins; 5, Allington Pippin; 6, not recognised; probably a local variety.—H. N. 1, Adams' Pearmain; 2, Belle de Boskoop; 3, King's Acre Pippin; 4, Court Pendu Plat; 5, Sturmer Pippin.

PEACH BORDER AND PEACH CASE.—J. B. Your natural gravel subsoil should be quite satisfactory with broken bricks and mortar rubble placed upon it. If you are in any doubt, put in a drain running parallel with the house. You need about nine inches of artificial drainage, with the smaller rubble on the top to prevent the compost from being carried down when the fibre of the turf has decayed. Allow a clear two feet of depth for the compost, and about four feet in width for young trees direct from the nursery, with a little extra width for prepared, home-grown trees. Peaches succeed best in a rather strong, calcareous soil, cut when dry, two to four inches in thickness, carted home and thrown into a heap until wanted for use. If time admits, chop the material roughly, throw it up in ridges, and leave it to sweeten. The corrective agents may consist of old lime and brick rubble, burnt earth, and road scrapings. To every four loads of loam add one load of these materials, thoroughly mixing all together and keeping the compost dry. Place the turves, grass-side downwards, over the drainage, and build up the retaining walls with turves as the border is made, and make all thoroughly firm. The compost suggested will be rich enough without the addition of manures, and will not force a stronger growth than is desirable; a bushel of crushed bones or bone-meal and a peck or two of soot may be added to every load of the compost in the case of lighter and poorer soils.

MARKETS.

COVENT GARDEN, Tuesday, December 13th, 1927.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Tuesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in the day.—EDS.

REMARKS.—Business conditions have shown a slight improvement during the past week, but owing to the increased supplies of Chrysanthemums fairly large quantities, especially of large blooms, have been left over each morning, while only the best marks in bunch stuff have realised anything like the price expected in December. Spray varieties now consist of Allman's Yellow, Baldock Crimson, Chestnut White, Heston White, Tuxedo, Negoya, Winter Cheer, Market Red and Bronze and Yellow Wilcox. Single varieties are now very moderate in quality and show signs of finishing for this season. Carnations increased towards the week-end, but they are not likely to become cheaper this side of Christmas. Roses are gradually declining in quantity and prices are on the up grade; the best sorts from home growers being Madame Butterfly, Golden Ophelia, Roselandia, Columbia, Richmond and Sylvia. Daffodils have already made their appearance, a few odd bunches being on sale last week. Tulips, on bulbs, are increasing in quantity and are chiefly scarlet and yellow sorts. Roman Hyacinths, cut and on bulbs, are now much better in quality; coloured Hyacinths are also offered in limited quantity. A few boxes of yellow and white Narcissi, from home growers, have been on sale during the past week.

FRENCH FLOWERS.—Paper White Narcissus has improved in quality during the past few days, and so also have single Violets. Supplies are now on the increase from France, the latest arrivals being Ulrich Brunner Roses in excellent condition, and Frau Karl Druschki—not so fine at present, but a welcome addition owing to the very small supply from home-growers. All Anemones and Ranunculuses are gradually improving in quality, as are yellow Marguerites and Mimosa (Acacia). Owing to the unfavourable weather conditions across the water only small quantities of flowers have arrived in a really good condition this season.

REMARKS.—There has been some slight improvement in many sections of the fruit market, conditions generally being more lively. Apples from the United States and Canada, although not plentiful, have increased in price, and there is a firmer demand for first-grade English Bramley's

Seedling and good Cox's Orange Pippin. There is a keener inquiry for Oranges and this is reflected in the higher prices now ruling. Hothouse Grapes continue in good demand and price levels are better. Some excellent Pears from California are offered, as well as a few from the Worthing district. French Beans from Guernsey are scarce and costly, in spite of heavy arrivals of Beans from Madeira. Hothouse new Potatoes are an improved trade, in addition to which there are supplies from the Azores and Scilly Isles. Tomatoes from the Canary Islands are plentiful and will be offered comparatively cheaply this week. Some really good new crop English Tomatoes have been sold at firm prices. Mushrooms remain in steady request with little or no fluctuation in selling values. Salads are moving out with more freedom, supplies being rather smaller. Cauliflowers from the West of England and Northern France are selling very much better and green vegetables generally meet an improved demand. Old Potatoes are selling fairly well with a satisfactory demand for the best class of tubers.

GLASGOW.

Prices of Chrysanthemums continue to favour the interests of the growers, and there is little prospect of reaction before the New Year. Several popular varieties, such as Almirante, Jean Pattison, Thorpe, Sandown Radiance, etc., are finished for the season, and although they have been succeeded by Winter Cheer, Baldock's Crimson and other December-flowering sorts, the daily supplies are not so plentiful as they were, and special quality blooms were particularly short in the Glasgow market during the past week. Messrs. Carnegie, Belmont Nursery, Ayr, received the top price of 3s. 9d. for 6's of Wm. Duckham, on Monday, and the average prices over the week were as follow:—W. Duckham, 2s. 6d. to 3s. 6d.; Phyllis Cooper and Mary Morris, special, 2s. 6d. to 3s.; ordinary, 1s. 3d. to 1s. 6d.; Ada Brooker, Framfield Pink, Winter Cheer and Red Lincoln, 2s. to 2s. 6d.; Favourite, 2s. to 2s. 3d.; Exmouth Crimson, 1s. 9d. to 2s. 3d.; Wilcox and Florrie King, special, 1s. 6d. to 1s. 9d.; ordinary, 1s. to 1s. 6d.; Pink and Bronze Pagam, 1s. to 1s. 3d.; Pink Triumph, 8d. to 1s.; Thorpe and Baldock's Crimson, 6d. to 1s. per bunch; Heston White, large, 6d. to 9d.; small, 3d. to 6d.; and Balcombe Beauty, 2s. to 3s. 6d. per dozen. Roses were dear again, pink varieties at 6s. to 8s. per dozen; red, 3s. to 4s.; Carnations, were steady at 4s. to 4s. 6d. and Narcissi, 4s.; Lilium longiflorum, 3s. to 3s. 6d. per bunch; Asparagus, large, 1s. 6d. to 2s.; small, 1s. to 1s. 6d. First consignments of Tulips and Ferns in pots experienced a slow sale at 1s. 6d. to 1s. 9d. each. The blooms appeared to have been subjected to excessive forcing.

THE WEATHER IN NOVEMBER.

The month opened abnormally warm and wet, with rather stormy southerly to westerly winds—a continuation of those experienced in October. This was terminated by numerous hail showers on the 5th to 6th, and the temperature then became considerably lower. The remainder of the month was mainly noteworthy for exceptional spells of northerly and easterly winds. The mean temperature of the entire thirty days was 43° 0', or 0° 6' above the average. Of bright sunshine, 6½ hours were recorded, or nine more than the normal number. Rain, however, fell on 19 days, or two more than the average, and the total amount was 4.28 inches, implying an excess of 1.21 inches. The subsoil water stood at a high level. Wind movement, after the first few days, was generally small, and only one very moderate gale was experienced. Haze and mist were of frequent occurrence, and fairly thick fog prevailed during portions of the 27th and 28th. There was no snow, and no special amount of frost. Joseph Baxendell, The Fernley Observatory, Southport.

GARDENING APPOINTMENTS.

Mr. John Lingwood, for the past eighteen months gardener to LORD FITZALAN, of Derwent, Cumberland Lodge, Windsor, and previously for twenty-five years gardener to the late W. G. RIGDEN, Esq., Queenswood, Englefield Green, Surrey, as gardener to Miss MAC-NOUGHTON, East Burnham Park, Farnham Royal, Buckinghamshire.

Mr. D. Boughtwood, as gardener to F. A. MORRIS, Esq., Bircher Hall, near Leominster, Herefordshire. (Thanks for 2/6 for R.G.O.F. Box.—EDS.)

Mr. T. E. Minn kin, for the past two years and nine months foreman at Newton Hall Garden, Stocksfield-on-Tyne, as gardener to J. E. DEUCHAN, Esq., Grey-court, Riding Mill, Northumberland. (Thanks for 2/- for R.G.O.F. Box.—EDS.)

The Dingle, Quarry Park, Shrewsbury.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the past fifty years at Greenwich, 38.9.

ACTUAL TEMPERATURE—
The Gardeners' Chronicle Office, 5, Tavistock Street,
Covent Garden, London, Wednesday, December 21,
10 a.m. Bar. 29.6. Temp. 39°. Weather, Wet.

Rothamsted Field Experiments

THE Field Experiments carried out at Rothamsted during 1925-26, an account of which is published by the Ministry of Agriculture,* help materially to advance knowledge of the modes of response of plants to fertilisers of different kinds. The chief problem which these experiments were designed to elucidate is why fertilisers of one kind or another act better in some seasons than in others. The fact that they do so is admitted and is illustrated by the Rothamsted results. For instance, the increase in hundredweights in yield of Potatos per hundredweight of fertiliser was found to range widely. With a nitrogenous fertiliser, sulphate of ammonia, it varied from twenty hundredweights in 1922 to twenty-five hundredweights in 1926. With sulphate of potash, without the addition of farmyard manure, the range of yield was extraordinarily wide—from fifty-eight hundredweights in 1922 to ten

hundredweights in 1924. When farmyard manure was used as well as sulphate of potash the capriciousness of reaction of the plant was no less, and indeed still more evident. An increase of twenty hundredweights was obtained in 1922, and no increase at all in 1924. Phosphatic fertilisers, as experiments on Swedes show, behave in like manner. A dressing of 600 lbs. of superphosphate gave an increase of 140 hundredweights in 1920, and a mere eighteen hundredweights in 1922. The valuable part of these investigations lies in the fact that they demonstrate the possibility of correlating the effects of fertilisers with the behaviour of the clerk of the weather. Phosphate and potash act best in a bad season. In the bad seasons 1913 and 1920, sulphate of ammonia, together with sulphate of potash, doubled the yield in the former year and trebled it in the latter; these increases, of course, representing the yield from the manured plots as compared with those from control plots with no artificials. On the other hand, an application of phosphatic fertiliser to the plots which in seasons of good weather (1922 and 1924) received sulphate of ammonia and sulphate of potash, produced a yet larger increase. The increases obtained by the use of nitrogenous and potassic fertilisers were far smaller—a matter of only two or three hundredweights; nor did the addition of phosphates make any considerable difference to the yield. It looks as though a new fertiliser maxim formulates itself from these results: "Take care of the bad and the good years will take care of themselves." There is, however, another aspect to be borne in mind. Crop and stock are continually removing the essential mineral substances, and particularly phosphates and potash, from the land. Therefore, if soil fertility is to be maintained these materials must be restored to the land from time to time. No less important is the conclusion to which the Rothamsted experiments point, that nitrogenous fertilisers may be relied upon to increase crop development in almost any season, whereas phosphates and potash, though they may not act in a good season will act energetically in a bad one. It would follow, as indeed Rothamsted experiments on Potatos show, that the best result is obtained from fertilisers when they are given a complete manure, that is, one containing nitrogen, potash and phosphates. The fact is that fertilisers of one or other of these three kinds are complementary to one another. This is strikingly shown in one of the experiments with Potatos. Sulphate of ammonia alone had little effect, but with the addition of sulphate of potash it brought about yields which rose with each additional quantity of sulphate of ammonia. The first hundredweight of the two fertilisers gave an extra ton of Potatos; the second hundredweight of each of the two fertilisers gave a further increase of one-and-a-half ton, and two more hundredweights of sulphate of ammonia gave again an increase of up to two tons, provided that the sulphate of potash was increased proportionately. Thus in 1926:—

| | Sulph. of Ammonia | 0 | 1 | 2 | 4 cwt. per acre |
|-------------------------|-------------------|-----|------|------|-----------------|
| 0 cwt. Sulph. of Potash | 7.8 | 7.7 | 9.4 | 9.5 | tons " |
| 1 " | 7.8 | 9.0 | 10.6 | 11.2 | " " |
| 2 " | 8.0 | 9.2 | 10.3 | 11.6 | " " |
| 4 " | 7.8 | 9.1 | 10.4 | 12.3 | " " |

Up to the point which the experiment reached, the largest quantity of properly proportioned fertiliser gave the largest increase of crop. Needless to say, however, this would not go on indefinitely, and therefore the problem for the grower is to discover where the limit of profitable increase comes.

Help for the Gardeners' Royal Benevolent Institution.—A highly successful whist drive and dance, organised by Mr. Charles H. Cook and the staff of the Royal Gardens, Windsor, in aid of the Gardeners' Royal Benevolent Institution, was held in the Guildhall, Windsor, on December 8. Thirty-four tables were occupied by whist players, while, at the same time, about eighty couples danced in the historic Council Chamber to music provided by an excellent local band. The Mayor, Sir William Carter, J.P., and two Town Councillors, paid a visit to the party during the evening. At the distribution of prizes, Mr. Cook thanked those present and the donors of the prizes for their help. At the close of the evening a member present explained the work of the Institution, and thanked Mrs. Cook and her band of helpers who provided and served refreshments to the company—which added greatly to the enjoyment of all. As a result of this effort, the Gardeners' Royal Benevolent Institution will benefit to the extent of about £40.

Water-colour Sketches at Kew.—The artistic attractions of the Royal Botanic Gardens, Kew, have been enriched by a number of water-colour sketches which were made towards the end of the nineteenth century by the late Mrs. Emma Hubbard. As the Kew Bulletin (No. 10, 1927) records, Mrs. Hubbard, at that time, lived at Kew, and the paintings are faithful representations of trees, flowers and garden scenes of the period. Mrs. Hubbard's son, Mr. George Hubbard, has loaned the thirty-seven pictures to Kew, and they are hung on the first floor of Kew Palace, where lovers of Kew may see them and, mentally, note the change time has made in the appearance of various specimen trees, several lake and woodland scenes, and the Bluebells in the Queen's Cottage grounds. The collection also includes a painting of the Seven Sisters Elms, the last of which was blown down nearly twelve years ago. Of very special interest to many, and especially to numbers of Old Kewites, is the painting of the old Kew Bridge which spanned the Thames for over a hundred years, and was demolished in 1899.

Chrysanthemums at Lyons.—The autumn show which took place at Lyons during November, although not solely composed of Chrysanthemums, was naturally dominated by that flower, the exhibits of which were fine enough and numerous enough to have constituted, alone, a very attractive show. The Paris firm of Vilmorin-Andrieux sent an exhibit as fine as any they are accustomed to stage in the capital, and that is saying a great deal; their exhibit was very varied, including plants trained in the Japanese style, in pyramid form, etc. Among especially fine varieties were Blanche Delclocque, Orleanais, Picard, and a very fine specimen of Cendrillon. Their group as a whole presented a striking effect, especially when viewed from the gallery above the hall. Near by, M. Guillot, of St. Marcellin, had a very handsome group, among which the variety Chrysanthemiste Lochot was especially noticeable. M. Martin, the well-known nurseryman of Digoin, showed Single Chrysanthemums in a very pleasing style; the soft, delicate tints and graceful groupings were a delight to the eye. Among others used to produce this pretty effect were Etoile du Nord, Leucanthemum, Madame Franchisseur and M. Malatier. M. Cornette, of Cognac, exhibited a fine new variety of his own raising, La Cagouille, an incurved sort, of pink-lilac hue; and M. Morin, of La Rochelle, brought his remarkable decorative varieties which are always so much admired. The Léonard-Lille Nurseries, of Villeurbanne, filled a large hall with a model garden, in which the beds were chiefly furnished with Chrysanthemums. A fountain, ornamented with statues, was illuminated, night and day, and presented a very beautiful effect, besides throwing into prominence the groups of huge specimen plants, about a hundred in number, including Edith Cavell, Ville de Paris and Ami Ph. Rivoire. M. Leloup-Grimoux, whose exhibit at the Paris exhibition won him a number of awards, including the Gold Medal of The Gardeners' Chronicle, showed some remarkable

new varieties, and also those of the previous year, including Commissaire Général Decault, Ami L. Ragot, and Com. J. Ragot. The modern garden staged by the well-known firm of Rivoire, père et fils, of Lyons, which occupied the whole of one end of the "covered way," was almost exclusively planted with Chrysanthemums. The design, which was of great originality, reflected considerable credit on the architect. The paved walks, with flowers growing in the interstices of the stones, the colonnade, the pergola, and the beds glowing with the rich colours of the Chrysanthemums, made a picture of real beauty, attained at a cost in labour, time, and inventive ingenuity, which only those who have such tasks to perform can possibly realise.

"The Garden."—It was with regret we learned that *The Garden* ceased publication with its issue for December 17. Under the guidance of its founder, Mr. William Robinson, *The Garden* enjoyed a long and useful career, and its usefulness was continued under the editorship of the late Mr. E. T. Cook, the late Mr. W. Harvey, Mr. H. Cowley and Mr. E. Cox respectively, and, latterly, by Mr. G. M. Taylor. This is the third of our contemporaries to cease publication since the first few years of the war.

Mr. John T. Jeffrey.—The Superintendent of the public parks at Edinburgh has been nominated President of the Royal Caledonian Horticultural Society, in succession to Mr. W. J. Thomson, who has held the office for two years, and retires at the end of December. This distinctive honour is well deserved, as Mr. Jeffrey has taken an active personal interest in the affairs of the Society and the exhibits arranged by the Parks Department have become an attractive feature of the monthly meetings.

The Dingle, Quarry Park, Shrewsbury.—Our Supplement Plate depicts the well-known "Dingle" in the Quarry Park, Shrewsbury, in its spring dress. Upwards of 12,000 Tulips were planted to produce this spring display, and the bulbs were supplied by Messrs. John Peed and Son, who kindly lent us the photograph from which our reproduction was made. The varieties were Pride of Haarlem, Erguste, McKinley, Rev. H. Ewbank, Viola, Valentine, Clara Butt, Negro, Moonlight, Fire Dragon, Louis XIV, Flamed Crown, Orange King, Royal Crown, Grenadier, Snowdon, Miss Jekyll, Glare of the Garden, Bronze Queen, Dom Pedro, Inglescombe Pink, Scarlet Emperor, and Old Times. Eight varieties of Wallflowers, four of Aubrietia, two of Myosotis, two of Polyanthus, and three of double Daisies, together with Arabis and Alyssum, assisted to produce a very beautiful effect in the spring of this year. Thousands of readers who visit Shrewsbury during the great Flower Show week are acquainted with the charming displays Mr. Arthur J. Ward produces in summer time, but comparatively few have seen the spring display in "The Dingle"—hence our Supplement Plate.

Honour for the Director of Kew Gardens.—At the University Commemoration, held at Adelaide on the 14th inst, the degree of D.Sc. *ad eundem gradum* was conferred upon Dr. A. W. Hill, Director of the Royal Gardens, Kew. Sir George Murray, Chancellor of the University, in conferring the degree, considered the University was honoured by the privilege of conferring the honour on such a distinguished scientist as Dr. Hill.

Wintry Weather.—At the moment of writing, practically the whole of the country is frost-bound. The actual temperatures are, generally, only of local interest, but, as illustrating the exceptional severity of the widespread cold, mention may be made of Falmouth, where something approaching a record has occurred. At this "Cornish Riviera" there have been hard frosts at night, and the maximum daily temperature last week-end was 35° Fah., while the frost continued all day at most southern seaside resorts. This weather will effectively test the hardiness of many of the recent plant introductions, as well as older subjects, and we confidently anticipate interesting communications from readers containing valuable comparisons and records. A short time in Covent Garden

Market early on Monday-morning reminded us of the anxieties that will beset readers whose greenhouse heating is none too effective, *i.e.* that special care and, at times, additional protection, is needed. In the market we noticed some consignments of *Lilium longiflorum* and of white Hyacinths in pots so frozen that the flowers had become almost transparent. We understand that considerable quantities of French flowers suffered similarly during transit. Needless to say, these plants and flowers had been packed in the normal manner, whereas a few extra layers of packing paper would most probably have saved them. The meteorological experts forecast a continuance of cold weather, so, if there is truth in the old saw that "As the days lengthen the cold strengthens," there is worse to come, and all wise gardeners will take measures accordingly.

Mr. George Ellwood.—It is no easy matter for a gardener, no matter how able he may be, to follow successfully one who has become widely known as a skilful cultivator and a very capable organiser. For many years before Mr. George Ellwood was appointed to the charge of the

MR. GEORGE ELLWOOD.

famous gardens at Swanmore Park, Hampshire, they had been closely linked in the horticultural world with the late Mr. Edwin Molyneux, who was a man of outstanding personality as well as a gardener of conspicuous ability. When it became known that Mr. Molyneux was to undertake the wider sphere of managing the whole estate, it was realised by all who knew, and they were many, that his successor would have no easy task in maintaining the gardens in their high state of efficiency. We may also state that the garden owner, W. H. Myers, Esq., who has so long been known as a "patron of horticulture"—as the old stylists would have expressed it—with a wide knowledge of gardening, must have fully realised this difficulty. The choice of a successor to Mr. Edwin Molyneux fell on Mr. George Ellwood. This was twenty years ago. Almost from the first it was seen how wise a choice it was. Not only at Swanmore Park itself has Mr. Ellwood made his mark as a gardener of exceptional attainments, but in his many exhibits at the R.H.S. shows he has shown the larger world his quality. Year after year, Mr. Ellwood has staged at the annual competitive shows of this Society garden produce of admirable and enviable high quality. At the fruit shows the names of "W. H. Myers, Esq., gardener Mr. George Ellwood," have appeared with unfailing regularity on the first prize card in the Southern Counties class for Apples, and times almost without number in the single-dish classes. At the annual

Vegetable Show, similar successes have been won, as the Sutton Cup and many R.H.S. Cups and Medals testify. At various provincial shows, Mr. Ellwood has continued his successes as an exhibitor of fruits, flowers and vegetables of very high quality. In his earlier days at Swanmore Park, Mr. Ellwood no doubt had the great advantage of having Mr. Molyneux near at hand should any need for opinion or advice arise, but, as always, time intervened, and Mr. Ellwood has continued his work with the same success as before. We have no doubt that he would unhesitatingly admit his good fortune in this matter, as he would in his early training. His initial training was at Aldenham House at a time when Mr. Edwin Beckett was busy making vast alterations and extensions to that famous estate, as well as growing plants and vegetables which won high honours at the shows. After working for eight years in various departments at Aldenham, Mr. Ellwood went to Lockinge Park, another famous garden, then managed by Mr. W. Fyfe, another famous gardener. At Lockinge, Mr. Ellwood also obtained experience in the production and arrangement of very high-class garden produce which was to stand him in good stead a little later. As older readers of *The Gardeners' Chronicle* are well aware, Lockinge and its gardener were synonymous with the best that was in horticulture. From Lockinge, Mr. Ellwood took charge of the gardens of C. R. de la Salee, Esq., at Enbridge Lodge, Newbury, where he successfully carried out many improvements in the pleasure grounds. Orchids were then grown extensively, and Mr. Ellwood raised some good hybrids of *Cattleya*, *Laelia* and *Cypripedium*. He soon became well-known as a successful exhibitor of stove and greenhouse plants and vegetables. After five years at Enbridge Park, Mr. Ellwood went to Swanmore. A man of pleasant, unassuming manner, Mr. Ellwood carries his many honours without affectation, and has endeared himself to his many friends.

Horticultural Exhibition at Antibes.—During the first fortnight of March next, the Horticultural Society at Antibes (Alpes Maritimes), will hold an exhibition which promises to equal in success that of 1924. It will take place in the Place Macé, and in the immense hall of the Grand Hotel, and the numerous classes are open to all horticulturists. A large concourse of visitors is certain to be attracted, and competition for space among exhibitors seems likely to be severe.

Winners of the "Gardeners' Chronicle" Medal in 1927.—Royal Caledonian Horticultural Society, Mr. John Gray, Middlewood, Uddingston; Shrewsbury Floral Fête, G. R. Mellor, Esq. (gr. C. Price), Tan-y-Bryn, Abergele, North Wales; Southport Show, Mr. James Gibson, Welbeck Gardens, Worksop; National Chrysanthemum Society, Captain R. B. Brassey (gr. James Quinn), Cottesbrooke Hall, Northampton; Midland Daffodil Show, Mr. H. A. Marriner, Little Brampton, Billingshurst; R.H.S. Amateur Show, (two Medals), Lionel de Rothschild, Esq. (gr. Mr. Bedford), Exbury, and Gerald W. E. Loder, Esq., Wakehurst Lodge, Ardingly, Sussex; Cheltenham Show, Mrs. Butler, Twynning Park, Tewkesbury; Guildford Gardeners' Society, Mrs. Farnham. The Heights, Witley, Surrey; Colchester Show, H. E. Theobald, Esq., The Rosary, Stanway Green, Colchester; Dundee Show, Mr. Richard Moore, 17, Cleghorn Street, Dundee; Paris Autumn Show, M. Leloup-Grimoux, Chrysanthémiste, La Mans, France; National Sweet Pea Show, Dr. A. V. Boyall, Kildare Lodge, Minehead, Somersetshire.

Public Parks at Königsberg, Prussia.—During the last few years, the ring of forts which surrounded the town of Königsberg, in Prussia, has been demolished, and the space thus available is being turned to good account to provide fresh open spaces, which will form almost a ring round the inner portion of the town. Preparations are being made to lay out the grounds in a picturesque and attractive manner with ornamental lakes, swimming baths, playing fields, and pleasure gardens; and in the heart of the town—for instance, on the former parade ground—many improvements

are being made, the former Reformed Cemetery being also made into an attractive open space laid out as a park. The allotment movement is being encouraged by the municipal authorities; there are at present about 2,800 allotment gardeners, but a large number of new allotments are being made, and laid out on a definite plan as part of the open spaces of the town. By the time the present arrangements are carried out, Königsberg will rank high among horticulturally developed municipalities, and will have good reason to be proud of its parks and gardens department.

Chrysanthemums in the Glasgow Parks.—The citizens of Glasgow are fortunate in the number and beauty of their public parks, also

Sunday—indicates the city dwellers' love of flowers.

Scottish Classification of Sweet Peas.—The Committee of the Scottish Sweet Pea, Rose and Carnation Society has compiled the following colour classification of Sweet Peas suitable for exhibition in Scotland:—Blue: *Blue Bird, Mrs. Tom Jones; Blush (pink): *Highland Mary, Dainty Maid, Elegance Improved, Valentine; Carmine: *Doreen, Renown; Cerise: *Charming, Coralline, Lucifer; Cerise (salmon): *Mrs. A. Searles; Cream: *What Joy, Matchless, Leslie Rundell; Cream Pink (pale): *Venus, Fair Lady, Cicely, Sunshine; Cream Pink (deep): *Picture, Mary Pickford; Crimson: *Sybil Henshaw, Unwin's Crimson, Red

been added. Comparison with the 1926 list shows that Charming is now preferred to Coralline; Mrs. Horace Wright supersedes Carmelita; Royal Pink takes the place of George Shawyer, and Model is starred instead of Avalanche. Charity drops out of the crimson class.

Appointment for the Ensuing Week.—THURSDAY, DECEMBER 29: Paisley Florists' Society's meeting.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Labourer's Cottage.*—Employ an honest working builder. Let the ground plan consist of two rooms only, thus: good kitchen, or living room, back kitchen or brew-house, fitted

FIG. 238.—CHRYSANTHEMUMS IN QUEEN'S PARK, GLASGOW.

in the number of winter gardens which are situated within the parks. The annual display of Chrysanthemums in the winter gardens at Queen's Park, Springburn Park, Tollcross Park, Botanic Gardens, and Glasgow Green, is something the general public have come to look forward to with keen anticipation. The accompanying illustration (Fig. 238) is from a photograph taken on December 8, in one of the Conservatories at Queen's Park. The display includes approximately 5,000 blooms in great variety, including Incurved as well as Japanese and decorative varieties. About a dozen incurved varieties are grown, including Alice Honor, Charles H. Curtis, Lady Donald, J. W. Streeter and H. W. Thorpe. Japanese varieties are very numerous, and among these are Bob Pulling, David B. Nicoll, Helena Margerison, Margaret McLeod, Mrs. Charles Russell, Mrs. Harold Wells and Viscount Chinda. A display similar to that depicted is provided at the other parks mentioned above, and the crowds who flock to the various parks to view the Chrysanthemums—especially on Chrysanthemum

Gauntlet; Flushed (pink): *Mrs. Horace Wright, Carmelita; Lavender: *Powerscourt, Austin Frederick Improved; Lavender (bluish): *Gleneagles, Mermaid; Lilac: *Lilac Queen; Maroon: *Warrior, Splendour, The Sultan; Mauve: *Chieftain, Royal Mauve; Orange: *Royal Sovereign, Guinea Gold, Wizard; Picotee: *Youth (white ground), *Sunkist (cream ground), Jean Ireland; Pink (orange): *Royal Pink, George Shawyer, Crusader; Pink (pale): *Radiance, Supreme; Pink (deep): *Pinkie, Hebe, Miss Philadelphia; Pink (salmon): *Magnet, Miss California; Purple: *Olympia, Purple Perfection, Royal Purple; Rose (carmine): *Private Jack Smellie; Salmon (orange): *Gold Crest, Fordhook Orange; Salmon (cerise): *Grenadier, Royal Scot; Scarlet (orange): *2LO (deep), Mammoth (pale); White: *Model, Edna May Improved, Avalanche, Constance Hinton. An asterisk denotes the variety which the Committee considers best in each section. Both the pale and deep bicolor classes and the deep blue section have been deleted, while cerise (salmon) has

up with all requisites of cooking, grate (Nicholson's of Newark), oven, and boiler, etc. A fire in this is used in summer, instead of in the kitchen, which is thus kept cool for the family. The two rooms should be so arranged as to lead out of and command a view of each other; a third room, or parlour, is worse than useless. Let there be three sleeping rooms, partitioned off for decency and illness' sake, with cellar and larder under ground. The house should be built of good hard brick or stone, and best lime mortar well bedded together to keep out damp. The roof should be overhanging, of blue tiles, with porches back and front, door-ways arranged to avoid draughts. Stained joists in floors, roofs, porches, etc., and plain brick-work without plaster, may be coloured and made to look well and save expense. Let the out-buildings be arranged tastefully and convenient and the garden ornamental. If skill, labour, and materials are good and well combined, you may, perhaps, keep within your limit, otherwise more than double it, and be no better off. *Anon. Gard. Chron., December 25, 1852.*

The Week's Work.

THE ORCHID HOUSES.

By J. T. BARKER, Dunstable, Bedfordshire.

Resting Period.—There are few matters more often misunderstood, or of more importance, than the resting or "ripening" of Orchids. Rest is not, perhaps, the proper term to use, as the plants are never actually at rest; what is required is a natural cessation of growth, so far as outward appearances go—for a longer or shorter period, according to the habit of the plant concerned. To induce this natural "rest" during winter, it is not only necessary to lower the temperature, but also to reduce the moisture in the atmosphere, and keep the plants more or less dry at the roots. Enough water should be given to prevent shrivelling, but the compost should not become a hard, solid mass for the want of it. Plants of the *Cattleya* family are sometimes greatly weakened by an insufficient supply of moisture during the winter and consequent loss of roots. Deciduous Orchids, such as *Calanthes*, *Catasetums*, *Chysis*, *Cynoches*, some species of *Dendrobiums*, and many others which lose their leaves entirely, seldom require water after the foliage has fallen, but should any of the plants show signs of shrivelling, water should be afforded, but no more given until the plants again show signs of distress. Evergreen, distichous-leaved Orchids, such as *Vandas*, *Saccolabiums*, *Aerides* and *Phalaenopsis*, require more moisture during winter than those with pseudo-bulbs. Very little water is, however, needed by these during the dull days of winter. If the *Sphagnum*-moss is in a live and fresh condition it will usually absorb nearly sufficient moisture from the atmosphere to provide for the needs of the plants. *Vanda teres*, and plants of a similar nature, will rarely flower well when treated like the other members of the family. These plants like a decided and long period of rest, and if kept without water for weeks together no harm will follow beyond the loss of a few of the older leaves.

Orchid Pests.—Opportunity should be taken, whilst the plants are at rest, to cleanse their surroundings, and to give special attention to the eradication of insect pests. The leaves of the majority of Orchids are fully matured, therefore the cleansing operations may be undertaken with little risk of injury. One of the worst pests of Orchids is scale, which conceals itself under the leaves and the outer sheaths of the bulbs. In cases of bad infestation the sheathing should be removed, and the plants thoroughly immersed in some safe insecticide. When cleansing the plants it is advisable to have a bowl or tub sufficiently large to permit the immersion of each plant in the insecticide; thoroughly wet the leaves and the pseudo-bulbs (but not the compost) to ensure the destruction of every insect. After withdrawing the plant, hold it over the bath to drain, and then place the pot on its side to allow the foliage to dry. Following this cleansing operation, each plant should be examined carefully and sponged, the pots made thoroughly clean and the plants re-staged, so that each receives the maximum amount of light.

THE KITCHEN GARDEN.

By R. H. CROCKFORD, Gardener to THE RT. HON. LORD WAVERTREE, Horsley Hall, Gresford, N. Wales.

Seed Orders.—Catalogues have already come to hand and no time should be lost in ordering the necessary seeds. Purchase from a reliable source as the best seeds are the cheapest. It is always interesting to test a few new varieties, but at the same time one should continue to grow those kinds and varieties that have proved suitable to the soil and climate of the district; for instance, a certain Pea may produce excellent results in one locality, and prove almost useless in another. No attempt should be made to

rely on old seeds of Parsnip, Parsley, Carrot, Salsify, Scorzoneria, Spinach, Onion or Beet, or disappointment may follow. When the seeds arrive, store them in a dry place. Seed Potatoes should be placed in trays, with the eyes uppermost, away from frost.

Rhubarb.—Where no forcing house exists and early Rhubarb is required, a start should be made now by covering a few good early crowns with pots, tubs or boxes, and placing fermenting materials (equal parts of leaves and manure) between and over them. This should give a gentle, lasting warmth. Good stalks may be expected in six or eight weeks. Failing manure, leaves will answer the purpose equally well, but a slightly longer period will elapse before the stalks are ready. Seakale may also be treated in this way, but all light must be excluded, or the stems will be badly blanched.

Tomatos.—Where a temperature of 55° to 60° can be maintained, seeds of Tomatos may be sown. Immediately these have germinated place them near the glass, in a light position, so as to promote sturdy growth from the start. Plants fruiting in pots should, for the present, be very carefully watered, and a dry, warm atmosphere maintained. Gentle stimulants may be given about every ten days, and the roots lightly top-dressed with good loam, wood-ash, and a little bone-meal so soon as they show through the surface soil. Fertilise the open flowers by using a camel-hair brush, or rabbit's tail, and rap the trellis about midday, when the pollen is dry.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to SIR CHARLES NALL-CAIN, Bocket Hall, Hertfordshire.

Indian Azaleas.—Plants of early varieties of Azaleas, such as *Deutsche Perle*, *Fielders'* White and *Hermosa*, may be placed in a little warmth and forced gradually to come into flower early in the New Year. Azaleas are subject to thrips, therefore the plants should be dipped or syringed occasionally with a solution of nicotine.

Coleus thyrsoideus.—This is now producing its flower spikes, and where the receptacles are well filled with roots, some reliable plant food may be given to assist them. This is a most useful plant to grow for producing flowers during the duller months of the year. The flowers last for a considerable time when cut.

Lasiandra macrantha.—Where blue- and purple-flowering plants are popular during the winter months, this plant is well worth growing; it is of easy culture. The correct name of this old garden plant is *Tibouchina semidecandra*.

Begonias.—Plants of the *Gloire de Lorraine* type should be removed from the show house so soon as the flowers have faded, and have their growths slightly shortened in view of procuring cuttings for next year. Retain only those plants that have made strong growths at the base. After the plants have been cut down they should be kept slightly drier at the roots for the next few weeks and in a somewhat lower temperature. After this short rest they may be brought into a temperature ranging from 65° to 70°, when basal shoots will soon be forthcoming to provide reliable cuttings. Experience teaches me that success with these Begonias depends largely on the constitution of the plants that are to furnish cuttings. Plants attacked with mite should be dusted with flowers of sulphur and the house vaporised with Campbell's vaporiser. Late Begonias that are being grown to furnish plants for decorating during January should receive liquid manure to assist them in the development of their flowers. B. Mrs. Peterson will be found a very useful variety for late use. Winter-flowering Begonias of the section represented by *Optima*, *Mrs. Heal*, *Exquisite*, *Ideala* and others, should, as they pass out of flower, be kept in a cooler house and allowed to become somewhat dry at the roots, but they must not suffer from an entire lack of moisture at the roots during the resting period, otherwise there will be losses.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to COLONEL SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Early Vines.—This is a good time to start the early permanent vines; the inside borders may be the better for another watering. If the vines are young and strong, clear water only, at a temperature of 80° will answer, especially if the border was well top-dressed. Old vines, on the other hand, cannot easily be over-fed; their roots may be watered with warm, diluted, liquid manure from the start. The syringe must be used to moisten old rods, especially near the pipes, and walls, floors and other surfaces. Here, as for pot vines, young canes being forced for the first time may be kept bent down, whilst old ones may be secured to the wires from the start. When well started, and all the buds are on the move, the young canes should be tied up to the wires without delay, otherwise the shoots will draw backwards to the light, and besides looking unsightly, they give unnecessary trouble in training. The temperature at this stage may range from 50° to 55° by night, and 60° to 65° through the day, with a rise of a few degrees with sunheat, but no advance should be made at night for the present.

Mid-season Vineries.—The vines should be pruned and the house cleansed and put in working order, but the vinery must be kept cool and airy to ensure a long and decided rest for the vines. If plants have to be kept in these vineries they should be of the hardiest nature, otherwise constant shutting up at night will affect the vines. All top-dressing and root work will have been finished, and the outside borders, if any, lightly covered with Bracken or litter to keep out frost. The roots, as a matter of course, will be quite moist enough, but if autumn watering was neglected it will be well to allow borders to remain on the dry side just after pruning.

Late Vineries.—Vineries in which ripe Grapes are hanging cannot be kept too cool and airy in mild, dry weather. A temperature of 50° is high enough for all black Grapes, but Muscats may be allowed 55° with a gentle circulation of fire heat when danger from frost is apprehended. The fall of the leaf is a trying time, especially in low houses, but damp may be counteracted by gathering the leaves daily and by warming the pipes on fine days and opening the ventilators. The lighter the firing and the steadier the temperature the better will the Grapes retain their colour and keep in a fresh, plump condition. Houses in which only a few bunches of ripe Grapes are hanging should now be cleared, not only for the sake of the fruit, but for the benefit of the vines. The Grape room is the best place for bottled Grapes, but when this structure is devoted to the storage of choice Pears, the gentle warmth so essential to the latter will fit it for the reception of Grapes. Artificial heat is necessary at times, but its constant use is almost as bad as an excess of moisture. If the Grape room can be kept cool and dry frost is excluded, and the ventilation perfect, Grapes will keep fresh and plump for months after they are removed from the vinery. When cutting Grapes before the leaves fall, the latter should be left to ripen and drop.

HARDY FRUIT GARDEN.

By H. MARKHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet, Middlesex.

Peaches and Nectarines.—Trees of Peaches and Nectarines have made plenty of growth this season, but the wood has not ripened satisfactorily. Where the leaves are adhering to the shoots a gentle shaking or brushing will reduce them and expose the wood to light and air, thus giving it a better chance to harden before frosty weather sets in. After the leaves have fallen, pruning and training is an easy business, provided proper attention was paid to disbudding and the removal of useless young growth during the growing season. As the fruits are produced on the young wood, care should

be taken to retain the best placed growths all over the trees, both for fruiting and also for replacing older growths; avoid overcrowding. A good Peach tree should be evenly balanced and thinly trained to the walls or wires. When pruning and regulating the branches of large-sized trees it is a good plan to commence on one side, remove the fastenings, and cut back unripened shoots to sound, firm wood, and to triple buds, or to a single wood bud. Sturdy, well-ripened shoots should be left at their full length. If scale is present, dress the affected parts with a nicotine insecticide, or any other suitable mixture, but always be careful not to use strong insecticides on young fruiting shoots or the buds may be injured.

Young Trees.—Planting may take place from now until next March. Only plant good varieties to keep up a lengthy supply of fruits. When laying the foundation of fan-shaped trees, keep both sides of the tree evenly balanced and do not encourage a central shoot.

Vines.—The pruning of all outdoor Vines may be carried out when the leaves have fallen. If done at this season the danger of bleeding is greatly lessened. Established canes should have their lateral shoots cut back to one or two plump buds, and younger vines, which have not reached their limit, should be allowed to extend two or three feet each season until they have filled their allotted space. Those about to plant young Vines should choose a warm position, facing full south. The drainage should be thorough, and the soil sweet and fibrous, with plenty of lime-rubble, wood-ash and crushed bones added; if the soil is heavy, the addition of charcoal will help to keep it sweet and porous.

THE FLOWER GARDEN.

By JOHN COUTTS, Assistant Curator, Royal Botanic Gardens, Kew.

Skimmias.—These attractive, dwarf, evergreen shrubs are useful for permanently furnishing a large rock garden, or the front line of a shrubbery. Their successful cultivation presents no difficulty as they thrive in a variety of soils. Their white, fragrant flowers are attractive, but the chief attraction is their bright red fruits. As they are dioecious, a few male plants must be planted to ensure a crop of fruits. *S. japonica*, of which there are quite a number of varieties, is the species most commonly seen in gardens; all the following are now known to be varieties of *S. japonica*, viz.: *S. fragrans*, *S. fragrantissima* and *S. Foremani*—male forms, *S. Veitchii* and *S. Rogersii*. Where they do not set fruit freely, *Skimmias* should be pollinated artificially.

Pernettya mucronata.—This is another dwarf evergreen shrub which is worth planting for its beautiful fruits; these fruits vary in colour from almost black to white, and are produced in wonderful profusion. The finest varieties, generally known as Davis's hybrids were raised by Mr. L. J. Davis, Hillsborough, Co. Down. They grow freely in sandy loam or in peaty soils and when in full fruit they are very attractive. Small, freely-fruited plants may be potted up for furnishing the cool greenhouse.

Iris foetidissima (The Gladwyn).—Irises are usually planted for their beautiful flowers, but this native species, with tall, purplish flowers, has no claim in that respect; it should, however, be more generally planted for the sake of its beautiful, orange-scarlet seeds, which are useful for winter decoration. The Gladwyn is suitable for planting with hardy Ferns, or in the semi-wild parts of the garden.

Danae Laurus.—The beautiful Alexandrian Laurel is more generally known as *Ruscus racemosus*. Its long sprays of glossy, green foliage are ideal for many floral arrangements, but apart from its usefulness in this connection, it is a fine garden plant that enjoys a moist, rich soil, and thrives in shady or partially shaded places. It is said to thrive on chalky soils, but I have had no experience of it in such conditions.

FOR NORTHERN GARDENERS.

By A. T. HARRISON, Gardener to the MARQUIS OF AILSA, Culzean Castle, Maybole, Ayrshire.

True Winter-flowering Plants.—It is at this season of the year that we appreciate most fully those plants which naturally produce their flowers in the open in mid-winter, and although it is not unusual in some seasons to find quite a variety of plants showing a few flowers, such as *Laburnums*, *Exochordas* and *Crinodendrons*, we know this effort on their part is untimely, and that their next season's display may be to a certain extent impoverished by it. This is not the case, however, with *Jasminum nudiflorum*, whose bright yellow stars are produced in mid-winter. The culture and propagation of this plant is of the simplest, as any fully established specimen will produce plenty of suckers, and if these are lifted carefully and placed in nursery rows, they soon make useful plants. Among other winter-flowering plants are the well-known *Viburnum Tinus*

ition; against a background of evergreens, its yellow, spider-like flowers are seen to advantage.

Polyanthuses and Coloured Primroses.—Very few seasons pass without some mention in the daily press of the precocious nature of these plants, and it is not always from the mildest parts of the country that the announcement is made. In our mild district, Polyanthuses and Primroses are almost continually in flower from November onwards, and cause no unusual comment. Where flowering plants are scarce, a number of these may be lifted and potted up, and placed in a cool house, where, if given plenty of air and water, they will very soon throw up numerous spikes, in the case of the Polyanthuses, and single flowers in that of the Primroses, and make quite a good show a few weeks ahead of those left out-of-doors.

Basic Slag.—The present time is, perhaps, the best in all the year for applying this useful manure. There are very few crops in the kitchen

FIG. 239.—ODONTONIA OLGA.

R.H.S. Award of Merit, December 13. Flowers white, with red spots on the lip.
Shown by Messrs. Charlesworth and Co. (see p. 493.)

which is covered with clusters of tiny white flowers from December onwards. All the members of the *Arbutus* family usually met with produce their waxy-white bells while at the same time carrying their crop of red, Strawberry-like fruits. *Garrya elliptica* is too well-known to need further commendation, but it seems a pity that so many of the male form have been planted to the exclusion of the female, with the natural result that seeds or berries are very rarely seen. Among the *Ericas* we have also some winter-flowering plants, and where Heaths do well they are worthy of extended culture; and *E. codonoides* is one of the best, producing, its pure white flowers from December to March while the earlier forms or hybrids of *E. carnea* are now commencing to make their annual display. The Glastonbury Thorn, *Crataegus praecox*, does sometimes make an effort and produces its clusters of Hawthorn-scented flowers in mid-winter, but apart from the legend attached to this variety, it is not a very conspicuous or interesting subject. The Witch Hazel, *Hamamelis arborea* is a decided acquis-

garden which do not benefit by its use. Fruit tree quarters may be given a top-dressing at the rate of four ounces per square yard, and when succeeded by half that quantity of kainit, and, if necessary, a similar amount of sulphate of ammonia in spring, a very complete and economical fertiliser will have been applied. The use of basic slag on lawns, however, is not recommended, as it tends to increase the growth of Clover at the expense of the fine grasses. Where farmyard manure is difficult to obtain, much may be done to eke out the scanty supply with these slow-acting chemicals, but when applying them they should be left on the surface and not dug into the soil, as the winter rains wash them down out of reach. Where club-root has been troublesome, these artificial manures appear less likely to spread and encourage this disease than manure which may have been obtained from a tainted source, while the application of lime, also on the surface, after digging, is a great help in combating this enemy of the kitchen gardener.

INDOOR PLANTS.

URCEOLINA PENDULA.

THIS quaint and very pretty bulbous plant is now somewhat rare in gardens, although once quite frequently seen. The flowers are pendant, the perianth yellow in the basal half, the remainder green and faintly margined with white, urn-shaped and about two inches long. The segments are lanceolate, the three outer ones rather longer than the inner ones; several flowers are produced in an umbel. The leaves are solitary, occasionally twin, erect, many-nerved and glabrous.

Urceolina pendula thrives in an intermediate

are finely displayed against the large leaves. *L. Hildebrandiana* enjoys a well-drained root-run of loam and peat, the former in preponderance, and ample "head" room is essential. In a favoured corner in some mild districts this great Chinese plant may succeed, but I doubt whether its full magnificence may be realised better than when it is seen festooning the columns and rafters of a spacious structure. R. A.

EUPHORBIA PULCHERRIMA.

WIDELY known and generally grown as Poinsettias, these plants have developed their brilliant bracts, and should be placed in a drier atmosphere and a somewhat lower temperature than hitherto, so as to prolong the

Or grown in pots, Camellias should be well supplied with water, for if the roots are allowed to become dry the buds that are now swelling will drop. Feed the roots with a concentrated fertiliser, or liquid manure, and make an effort to cleanse the foliage before the flowers commence to open. T. P.

ORCHID NOTES AND GLEANINGS.

SELENIPEDIUMS.

MEMBERS of this once popular group are still worthy of a place in collections, and will undoubtedly come back to favour and be as popular again as they were in the past. There are numerous beautiful hybrids, whilst some, such as the *C. caudatum* hybrids, with their long tails, are most attractive at whatever season they bloom. Plants that are root-bound and require repotting may be attended to, even at this season, using a similar compost to that usually recommended for the green-leaved, winter-flowering kinds.

The usual caution necessary in regard to watering newly-potted plants must be strictly observed at this season of the year. Each plant should be kept plump and healthy, for if the leaves are allowed to lose their fresh and robust appearance through dryness, they rarely, if ever, recover. Most members of this section of *Cypripediums* succeed in a lower temperature than do the summer- or the winter-flowering kinds, and a cool *Cattleya* house temperature will answer their requirements. J. T. B.

VANDA SUAVIS AND V. TRICOLOR.

THESE magnificent Vandas were introduced by Messrs. J. Veitch and Sons, from Java, about 1846, where they were discovered by Thomas Lobb.

The two species are associated in their native home, and have often been imported together; the structural differences are small, hence a little confusion has long existed, some authorities according to both specific rank, others making *suavis* a variety of *tricolor*, and yet others describing *tricolor* as a form of *suavis*.

The leaves of *V. tricolor* are curved, imbricating at the base and unequally two-lobed at the apex; the scapes are stout, several-flowered, ascending or spreading. The flowers are two inches to three inches across, fleshy and fragrant; the sepals and petals are whitish-yellow, spotted with reddish-brown. The lip is three-lobed; the side lobes small, erect, rounded, white; the mid-lobe magenta-purple, white at the base, with some suffusion or streaks of reddish-brown on the basal area. The lip is slightly convex above, with three ridges; the spur is short, compressed, white, and the column is swollen laterally at the base.

In *V. suavis*, the sepals and petals are white, spotted and barred with red-purple; the lip is three-lobed, the middle or front-lobe narrow, the basal half rich purple, and the apical half of paler colouring, the side-lobes being deep rose-purple.

These magnificent Vandas vary in height, under cultivation, from one foot to five feet, and the leaves are twelve inches to eighteen inches long; the plants may be grown in pots or pans half filled with crocks. *Osmunda* fibre is the best rooting-medium, with a surfacing of live *Sphagnum*-moss. Root disturbance is inimical to success, so that repotting should not be undertaken until it becomes an absolute necessity. Leggy stems—and these are not unusual—may be carefully reduced when root action commences, unless the appearance of basal growths should render this unnecessary.

The Vandas here described require a temperature of a stove house, considerable atmospheric moisture and shade from direct sunshine; a dry condition at the roots will not be tolerated, but during the winter months considerable care should be exercised when watering.

A large, well-flowered plant of *V. tricolor* or of *V. suavis* is a fine sight—it is a combination of glorious colouring, fine proportions and graceful port; the largest and best-flowered plants I have known were accommodated in a warm house with a north exposure, and placed on staging fixed over a water tank.

FIG. 240.—FLOWERS OF THE SERVICE TREE.
(see p. 504).

temperature, the cultural treatment required being similar to that provided for *Hippeastrums* except that the "rest" should not be quite so pronounced as that required by the better-known plants. Popularly known as the Drooping Urn Flower, *U. pendula* is synonymous with *U. aurea*. A native of the South American Andes, it is figured in *Bot. Mag.*, t. 5,464 and has been referred to *Collania urceolata*. Other species of *Urceolina* are *U. latifolia* and *U. miniata*, both uncommon in cultivation and scarcely known outside botanical collections. A.

LONICERA HILDEBRANDIANA.

THIS magnificent Honeysuckle is very suitable for cultivation in a large and lofty conservatory or greenhouse. The clusters of big, trumpet-shaped flowers of bright and exceedingly attractive orange colouring—not, perhaps, produced with any great degree of freedom—

life of the "heads." Poinsettias are excellent plants for bold grouping and may be used in a cut state, provided the cut ends are dipped in hot water. Poinsettias dislike the careless application of water to their roots as well as sudden fluctuations of temperatures; errors in these respects will be followed by loss of foliage.

CAMELLIAS.

WHETHER Camellias are grown in pots or planted out in borders, they will be found to thrive best when grown under the very coolest conditions. When it is remembered that Camellias will thrive and produce a serviceable supply of flowers when grown out-of-doors in sheltered positions, it is a matter of surprise to discover how much the plants are coddled in some establishments.

But whether planted out in greenhouse borders

The Chatsworth variety of *V. suavis* has its sepals and petals profusely spotted and streaked with blood-purple; the lip is rosy-purple, suffused with a deeper shade. In the variety *Sanderæ*, the flowers are pure white, spotted with light, greenish-yellow. Another varietal form is *Gottschalkæi*.

V. tricolor planilabris is a fine variety; its flowers are larger than those of the type, the sepals and petals being yellow, marked with brown, while the large lip is rose, margined with purple, and has a white basal area. The variety *insignis* must not be confused with the species *V. insignis* (Blume) from Malaya.

These fine Orchids will sometimes flower two or three times during the year, and should certainly again receive the attention they once enjoyed. *A. C.*

ALPINE GARDEN.

SAXIFRAGA L. C. GODSEFF.

VARIOUS names appear to be applied to this charming hybrid *Saxifraga* of the *Burseriana* section, and occasionally it is spoken of as *S. Godseffiana* or *S. × sancta speciosa*. It is one of the hybrids which derive their origin from *S. sancta* and *S. Burseriana speciosa*. It has the habit of *S. Burseriana*, and forms little mats of green, shiny foliage and, very early in the year, gives an abundance of its small, bright yellow flowers. It is an easy grower and flowers freely every year. *S. L. C. Godseff* delights in a moraine or in light gritty soil in the rock garden. I always prefer to give it a sunny position.

POLYGONUM EQUISETIFORME.

THE *Polygonums* or Knotweeds are almost protean in their form, and it is difficult to realise that certain of their number are allies of some of our common and often troublesome species, which sometimes appear to set themselves out, not unsuccessfully, to monopolise much of our garden space. There are some which are mere weeds, with no claim to beauty, but there are others of the greatest charm and claiming universal admiration. Others, again, are marked by some striking feature which gives them high claims upon us.

The one under notice, *P. equisetiforme*, is among the last class, and is a plant markedly divergent from the "beaten track" of the race. It may be said to be a Knotweed masquerading as a Broom, and one of its synonyms is said to be *P. scoparium*, although a reference to the *Index Kewensis* does not quite support the late Mr. Reginald Farrer's statement to that effect.

However that may be, this is a plant of much interest, which grows about two feet or so high, and produces numerous, wiry branches like those of some of the lighter Brooms, and totally unlike most of its congeners. In late summer and autumn it bears many small, white flowers, and the whole appearance at flowering time is very graceful. The late Mr. Farrer wrote enthusiastically in its favour, suggesting that it should be planted on the top of a sunny elevation where it would fall and partially veil the rock, but it is quite a good border plant, and seems to remain fairly erect there without assistance. It is one of the many rare plants at Monreith, and hardly ever fails to attract the notice of interested visitors to that wonderful garden. *S. Arnott.*

BELLIUM MINUTUM.

THIS tiny Daisy is a delightful little plant for a sunny, well-drained spot in the rock garden; it will furnish a beautiful pan for the alpine house and is eminently suited for use in the rockwork of a fascinating alpine house. The tiny, white flowers have the very faintest suffusion of pink colouring; they are not more than half-an-inch in diameter, and surmount slender stalks that are longer than the foliage. This species flowers from June to September, and is not more than three or four inches in height; the small leaves are narrow, attenuated at the base and slightly hirsute. Thriving

in sandy loam and peat, propagation of *B. minutum* is readily effected by seeds or by division in spring.

This interesting little plant was introduced from The Levant in 1772, and is a delightful companion to the Algerian Daisy, *Bellis rotundifolia coerulescens*. *Bellium* is very near to *Bellis* and very like it in appearance. *Ralph E. Arnold.*

SHORTIA GALACIFOLIA.

It is not difficult to understand the favour with which *Shortia galacifolia* is viewed by those who own rock gardens in which it is a pronounced success. These are many, for the plant is not one presenting untoward difficulties of culture, and its intrinsic beauty is so great that those who have it never weary of sounding its praises,

BOG GARDEN.

SAXIFRAGA PELTATA AND GUNNERAS.

THIS fine plant, with its large, handsome leaves, is an ideal subject for planting along the lake- or stream-side, as well as for the bog garden, large groups of it being very effective arranged with other plants, such as *Gunneras*, *Rodgersia podophylla* and the newer *R. pinnata*, which is very handsome, with its big inflorescences of rosy-red flowers and handsome bronzed foliage. They all enjoy a free root-run with plenty of humus in the soil.

Gunneras, which cannot withstand severe frosts, should be protected against possible injury by having dry leaves or Bracken placed round them, covering the whole with their own leaves. *Gunneras* are very handsome when

FIG. 241.—FRUITS OF THE SERVICE TREE.
(see p. 504).

or dwell with enjoyment upon their plants in growth. It is charming alike when in bloom and out of flower. When in flower in spring it delights us with its nodding flowers of white or pinkish-white, and, later, the graceful, persistent leaves are marbled in a most exquisite way with crimson, pink and ivory white. These charms cannot be ignored, and so *S. galacifolia* remains a high favourite with the alpinist. Its principal requirements appear to be a free soil of leaf-mould or peat, with sun, if we are to reap the full enjoyment of the colouring of the foliage. The white form is very beautiful but some have a preference for the rose-coloured one, *rosea*. Both respond to the same treatment, and it may be well to mention that it is better to pay a good price for a large plant established in a pot, ready to turn out, rather than pay less and have a small specimen that will take a long time to establish itself.

S. galacifolia is a much easier plant than its lovely Japanese cousin, *S. uniflora*. *S.*

planted near the margins of ponds, or streams, or in moist, sheltered positions; they require a large and rich root-run. The planting site should be prepared with good loam and plenty of well-rotted manure; established plants should have a heavy dressing of rotted cow manure each spring. *J. C.*

VIOLA HOWELLII.

THIS delightful little Violet from north-west America has reniform leaves of a most refreshing shade of green; the small flowers, freely produced, are clear yellow and in evidence during the greater part of the year.

During the last two or three seasons, this species has been remarkably effective in a moist peat bed, in company with dwarf *Rhododendrons*, *Meconopsis*, *Dodecatheons* and *Smilacinas*. It increases apace and is always of cheerful appearance; it thrives, however, in almost any ordinarily good soil, and prefers a moist situation in half shade. *R. A.*

HARDY FLOWER BORDER.

VERBASCUM.

THE Mulleins are peculiarly suitable for grouping in the hardy flower border and in the wild garden, while, if colonised in the woodland, their stately port and soft, but effective, colouring rarely fails to arouse admiration. The foliage of the larger species and varieties is undeniably handsome, and where the plants appear in generous masses, the effect of the amply-proportioned and somewhat hoary leaves is noble. The majority of cultivated *Verbascums* are best treated

a colony of plants is most effective; it is an old plant in gardens, as it came from southern Europe so long ago as 1796.

V. phlomoides, the Woolly Mullein, has fasciated yellow flowers on three-feet spikes, and handsome foliage; a fine species and one of the oldest in cultivation; it was introduced from southern Europe in 1739.

V. ovalifolium is a dwarf species from Tauria, whence it came in 1804; the large flowers are orange, with purple filaments, and the leaves are ovate. *V. cupreum* is a very pretty, dwarf plant, probably a form of *V. phoeniceum*.

V. Chaixii, the Nettle-leaved Mullein, produces yellow flowers in loose, many-flowered

Attractive hybrids of comparatively recent introduction include *Caledonia*, three feet, sulphur-yellow, shaded bronze; *Miss Willmott* pure white, four to six feet; *New Departure*, buff-yellow, three to five feet; *A. M. Birnie*, six feet, rosy-fawn, a beautiful variety; *Harkness's* hybrids; *Cotswold Queen*, crushed strawberry, beautiful and unique; *Beauty*, biscuit, shaded purple; and *Gem*, bronzy-yellow, shaded purple.

The genus *Verbascum* is represented in our native flora by several species: *V. Thapsus*, *V. Blattaria* (probably introduced), *V. virgatum*, *V. nigrum*, *V. Lychnitis*, and *V. pulverulentum*. Bentham and Hooker record that "The genus extends over Europe and northern and central Asia, but is most abundant in the Mediterranean region, where the species vary much, besides frequently producing natural hybrids, so that their distinction has become very complicated." *A. C.*

LATHYRUS ROTUNDIFOLIUS.

ONLY a limited number of the perennial climbing Peas are much seen in gardens, and of these *Lathyrus latifolius*, the common Everlasting Pea, is the general favourite. It is a pity, though, to neglect some of the others, and a comparatively low-growing species, *L. rotundifolius*, is a plant which ought to be borne in mind. Roughly speaking, it is about five feet high, and is excellent for climbing up a low trellis or over a small shrub. It is many years since it was first brought to the notice of the writer and a number of other hardy plantmen by a now departed hardy plant grower whose contributions to the horticultural press were always instructive and interesting. It proved worthy of his commendation, so pretty was this slender-growing, dwarf climber, with its brightly-coloured flowers.

L. rotundifolius is of slender growth and has, in early summer, heads of small, salmon-scarlet flowers. This verbal description comes far short of conveying adequately the brightness of this perennial Pea. It is hardy, and may be raised from seeds, sown under glass in spring or in the open in May or June. It should have a sunny place. *S.*

TREES AND SHRUBS.

A FINE SERVICE TREE.

AT the suggestion of Mr. W. J. Bean, I send you the following notes on a fine specimen of the true Service Tree (*Pyrus domestica*, Linn.), which it seems desirable to put on record. The tree is growing in a sloping meadow belonging to Beech Hall Farm, about ten minutes' walk from my house, and is almost on the left bank of the Ching Brook, which runs between the meadow and the gardens of the houses in a neighbouring road.

Beech Hall itself, with its immediate grounds, is in the market, but I understand that the farm and meadow are not included, so the tree is safe from the builder and road-maker for a time; but bricks and mortar are encroaching so steadily on the country hereabouts that it cannot be many years before this farm property is overrun, and then the tree will have to go, unless by a fortunate accident it should happen to fall within the surveyor's plans to include it in one of the gardens, or, much better, retain the whole meadow, with the tree, as an open space.

The photographs here produced will give a better idea of the tree than any amount of description, so I need only add that its height is about sixty-five feet, and the bole diameter at five feet from the ground (*i.e.*, just below where it divides into five great limbs) is three feet six inches (Fig. 242), the greatest spread of foliage being about eighty-five feet. Figs. 243 and 244 are views from the south, and Fig. 242 from the north, the hazy buildings in the background being those of the farm.

The tree flowers and fruits freely in favourable seasons, and it will be seen from the photographs that the leaves (Fig. 241) are very similar to those of the Mountain Ash, but the serrations are much more acute than in that tree. The

FIG. 242.—BOLE OF THE SERVICE TREE AT HALE END.

as biennials, and their cultural requirements in any ordinarily good soil are of the simplest.

V. olympicum is a stately plant with a candelabra-like stem, five to six feet high; the flowers are individually large and bright golden-yellow. The woolly leaves are broadly lanceolate, acuminate and very handsome. This popular species was introduced from The Levant in 1883.

V. phoeniceum is a charming species and one worthy of extended cultivation; the colouring of the flowers ranges from pure white to shades of red, pink, violet and purple. This somewhat slender plant grows two to three feet high, and its leaves are glabrous above and pubescent beneath; the flowers are loosely and elegantly arranged upon the stem. This Mullein is often increased by self-sown seedlings, and

fascicles; the leaves are crenate, tomentose beneath, and the height of the plant is about three feet. This species is widely distributed over southern and central Europe, and was introduced in 1821.

V. longiflorum is a beautiful plant with greyish-white foliage of tropical appearance and huge spikes, six feet high, of yellow flowers. *V. Libani* has an imposing inflorescence of yellow flowers and bronzy foliage; the plant reaches a height of five feet. *V. densiflorum*, with stout spikes of coppery-yellow blooms, is very attractive, and is about three feet in height.

Other species deserving of mention are *V. vernale*, with immense spikes of yellow flowers; *V. Wiedmannianum*, violet-red, a fine plant; and *V. leianthum*, with huge pyramids of yellow flowers.

fruits (Fig. 241) are greenish-brown when ripe and rather smaller than Medlars, so they cannot possibly be mistaken for those of the Mountain Ash. The flowers are shown in Fig. 240.

Besides this noble tree, there is another of the same species growing in the front garden of a house in a neighbouring road, and this is about thirty feet high, has a trunk seven-and-a-half inches in diameter, and also flowers and fruits freely in favourable seasons. *C. Nicholson*, 35, The Avenue, Hale End, Chingford, E.4.

CLERODENDRON FOETIDUM.

THOUGH cut well back during winter, this handsome *Clerodendron* is a useful subject for planting against a warm wall. It sends up numerous stout, sparsely-branched growths every year, these reaching three feet or more in height. The growths are clothed with large, handsome, heart-shaped leaves, from three to eight inches in length, coarsely toothed at the margins, and dark-green in colour; the veins on the under-surface are covered with reddish down. The leaves are borne on rather slender, downy petioles, from three inches to five inches in length.

The flowers, produced in closely-packed corymbs early in September, remain effective until destroyed by frost; they are rich purplish-red in colour and sweetly-scented. The specific name has reference to the leaves, which, when crushed, emit a foetid odour. *Clerodendron foetidum* is easily increased by the removal of the freely-produced suckers. The species was introduced from China by Fortune in 1844. *A. G. F.*

RUBUS GIRALDIANUS.

THIS is undoubtedly one of the best of several species of Bramble which are rendered conspicuous during the winter time by the colour of their stems. Seen from a little distance, it would appear that they have been whitewashed, but closer inspection shows that the whiteness is really due to a mealy, waxy secretion which covers the bark. It is difficult to imagine a more beautiful winter picture than a group of this Bramble planted in front of a dark back-

in having more arching, pendulous stems, which give to it a more graceful habit, and in having, usually, nine leaflets instead of the three to five leaflets of *R. biflorus*.

year's wood so soon as it has flowered and fruited, thus exposing to view the full beauty of the current year's stems. Pruning is usually carried out in August. *T. H. Everett.*

FIG. 243.—THE FINE SERVICE TREE AT HALE END; IN WINTER.

Cultivation presents no difficulties; the best results are obtained when it is accommodated in a good, loamy soil, deeply worked and enriched with a liberal dressing of well-rotted manure. A mulching of manure should be

HIPPOPHAE RHAMNOIDES.

OF the many shrubs advocated for winter effect in the garden, the Sea Buckthorn undoubtedly ranks among the foremost. It is a deciduous shrub, sometimes attaining the dimensions of a tree, and although, as its popular name implies, it is generally to be found near the coast, it nevertheless thrives inland, and is very effective if planted on the margins of ponds or streams.

It is unisexual, and should be planted in groups of five or six, one of which should be a male plant. It is of rather stiff habit, the short, young growths, which are often terminated with sharp spines, being covered with silvery-grey spines, while the narrow, almost sessile leaves are from one inch to three inches in length and tapering at both ends. They are dark, greyish-green above, the scaly undersides being silvery-grey.

The insignificant flowers are produced in April, in clusters, on the growths of the previous season, those of the female plants being followed by a profusion of fruits which are ripe by September and retain their colour throughout the winter. They are rounded, or egg-shaped, rich orange, and although so brilliant are untouched by birds because they are strongly acid.

Hippophaë rhamnoides may be propagated either from seeds or by layering, the latter method being best where the sex of the plants has been determined. *A. G. F.*

PITTOSPORUM TOBIRA.

THIS sweetly-scented, evergreen shrub was introduced into this country from Japan in 1804. Its white flowers are useful for decorative work, and small plants are suitable for greenhouse and room decoration.

Our specimen grew too large for these uses, also for arranging with the Oranges and similar shrubs out-of-doors during the summer months, so it was planted out several years ago. It has safely weathered the winters, and is now a healthy, vigorous shrub in the pleasure grounds.

The flowers commenced to open on December 7, and at this early date were very effective. The only protection our plant receives is from some large shrubs growing some distance away, which break the cold winds. *G. Emmett, Lydney Park Gardens.*

FIG. 244.—THE FINE SERVICE TREE AT HALE END; IN SUMMER.

ground of evergreen. *Rubus Giral dianus* was introduced to Britain from China about twenty years ago, and has proved equal in all respects to the much better known *R. biflorus*. *R. Giral dianus* differs from the latter species

given annually, the aim being to encourage the formation of vigorous growths, as these colour much better in winter than the weaker shoots.

Pruning consists in cutting out the previous

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C. 2.

Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.

Urgent Communications.—If sent by telegraph, these should be addressed "Gard. Chron.," Rand; or by telephone, to Gerrard, 1543.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Letters for Publication as well as specimens of plants for naming, should be addressed to the EDITORS, 5, Tavistock Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.

BURMESE SPECIES OF MECONOPSIS.

THE garden value of the Poppyworts as a whole is still a moot point. A dozen species—*M. Prattii*, *M. integrifolia*, *M. latifolia*, *M. Wallichii* and *M. Baileyi*, for example—have established reputations, but the genus, as a whole, is more popular in literature than in life. But the Poppyworts are, after all, comparatively *nouveaux riches*, and have yet to settle down in public life. Besides, enthusiasts having bowed down and worshipped them blindly, were frankly grieved at their early failure, which was too often a state of suspended animation. Nevertheless, the faithful never cease to proclaim their virtues, and only the most fanatical Tories can blind themselves to the fact that in another decade the first dozen will have been raised to the garden peerage, with a second dozen in close support.

Until recently, the Burmese Alps had yielded only three species of *Meconopsis*, none of them new. The first found, in 1914, was *M. Wallichii*, var. *fusco-purpurea*, which I collected in the Hpimaw Hills. It was collected again in 1919, both by Reginald Farrer and myself, in the same general region, when Farrer also collected the tiny, pale-blue *M. lyrata*. Whether this last has ever been raised from seeds or not is a matter of complete indifference as it is a wretched dwarf. Finally, in October, 1922, when crossing from Yunnan to Hkamti Long, I collected *M. impedita*, in fruit, above the Taron gorge, just overlapping into Burmese territory; it is widely distributed in western China, but so far has resisted all attempts to domesticate it.

It may be noted that none of the three are exclusively or even typically Burmese; two of them, indeed, rather luckily, spill over into the high frontier mountains which, being the home of the Irrawaddy, we euphemistically call Burma. The third, *M. lyrata*, is a true Indo-Himalayan alpine, found on the rainy ranges between the snows and the Indo-Malayan jungle down below. In the extreme north of farthest Burma, however, where the wandering threads of the myriad mountain ranges are ravelled up to buttress the Tibetan plateau, the genus shows a quite remarkable expansion; so much so, that in the valley of the Seinghku, in 1926, I collected six species, five of them new to Burma, and I have little doubt there

are others awaiting discovery. Of these five species, three are entirely new, the remainder new varieties; bringing the known Burmese Poppyworts up to eight.

July is the time to find the Poppyworts in flower, and not even the most advanced array themselves before the middle of June; consequently, one can glean quite a lot of information about them in the early summer before they flower as either their fruits persist from the previous winter, or their foliage does. But of seeds one can find no trace, as they rid themselves of these very completely at an early date, assisted by troops of ravenous grubs.

Early in June, in the upper Seinghku valley, I marked down three species, two with persistent foliage rosettes, which had survived the winter beneath the snow quilt, the third conspicuous by reason of its capsules. One closely resembled *M. Baileyi*. The second, with a great rosette of gold and green leaves, suggested *M. Wallichii*, although the leaves were more closely and deeply cut, and the capsule more like that of *M. robusta*, so that I expected a new species. The third, judging from the shower of capsules, sang a song of *Bellae*, and I guessed it to be *M. impedita*.

After the middle of June, the snow began to melt very fast, and one by one the Poppyworts romped into bloom, the azure Jewel of the Meadow, *M. Baileyi*, leading the way. Apart from certain technical characters which do not quite fit, this was a meadow form of the peerless, Tibetan *M. Baileyi*, and I have called it variety *pratensis*. It might equally well be regarded as a variety of the Chinese *M. betonicifolia*, being intermediate between the two. *M. Baileyi* var. *pratensis* was the commonest kind in the valley, occurring in hundreds between 10,000 and 12,000 feet, on steep alpine meadow slopes, and lasting until the end of July. Petals four. Flowers sky-blue, with trembling, golden anthers, concealing the barrel-shaped, star-crowned ovary in the centre. Height, three feet; polycarpic. This variety should do at least as well as *M. Baileyi*, and might withstand more sun.

The second species to flower, at the end of June, was the supposed *M. impedita*, now *M. rubra*. The first flowering specimens encountered were leaning from crevices in the gneiss cliff at 14,000 feet altitude, a never-to-be-forgotten sight. The foliage was more like that of the dainty, blue-flowered *M. bella* from Sikkim, but the habit was perfect *impedita*. To the colour of the flower, however, I at first attached little importance, thinking that I gazed upon a freak; but when ten days later every scree and rubble-chute threw up fountains of blood-red Poppy flowers, no longer could I conceal from myself that I had stumbled upon a prize.

M. rubra may be described as a red-flowered *M. impedita* with six petals. There are other purely technical distinctions, but the habit is the same in both, though *M. rubra*, like *M. horridula*, sometimes tries to build up a central stem of agglutinated scapes. The usual form, however, is a number, often a large number, up to twenty even, of independent one-flowered, basal scapes, not above six or eight inches high. To say that the flowers are red is tame enough, and yet startling. There was no question of freaks; I saw hundreds of plants, and the colour never varied a semitone. When, as often happened on a steep face, a sun shaft, loosed from the cloud rack, drove clean through a flower, it flared up in a jet of scarlet flame. Even on the dankest day, when the reeking valley smoked and dripped forlornly, and the cliffs were blotted out in the driving drizzle, the colour was that of a glowing port-wine-red, which nothing could dim. Towards the middle of July, every stone-chute and gravel-bank between 11,000 and 12,000 feet incandescenced with scores of twinkling red lights as a flash of sunshine touched off the flowers. *M. punicea*, one of the lost causes, has been cited as the red Poppywort, but *M. rubra* has nothing to learn from *M. punicea*. Unfortunately, *M. impedita* has been the despair of gardeners in Britain, no less than *M. punicea*; let us hope that *M. rubra* will settle down in exile.

At the end of June, I saw *M. lyrata* on the steep alpine slopes. It is a quaint, anaemic-looking scrap of a plant, scarcely three inches high, bearing one, or sometimes two, nodding,

four-petalled flowers of a washy blue; and at first sight it is hard to believe that this pale weakling is closely related to the gorgeously-coloured, pontifical Poppyworts of the 'Grandes' group.

M. lyrata languishes on the turf or gravel slopes above 12,000 feet, and though nowhere abundant, is widespread and moderately common. Sometimes it is completely overshadowed by tall, rank-growing herbs, but generally it favours the open. It is one of those elusive wraiths which one never seems to find in fruit at the spot marked, but which is continually thrusting itself into notice at unexpected places, as though to make amends. The tiny, faded-blue flowers are not attractive, and the species is chiefly of interest for its distribution.

In July, the strange *Meconopsis* flowered. For days I watched the tall stem drawing out from the thickest crown of leaves, and knew that it was not *M. Wallichii*, nor yet *M. robusta*, nor *M. paniculata* either. And at last the topmost flower swelled till it burst its bonds, and the crumpled petals shook themselves out in fold after fold of shimmering violet *crêpe-de-chine*; and those below followed fast. Here, indeed, was a stalwart, worthy to rank with the champions of the genus, *M. Wallichii*, *M. paniculata*, *M. Baileyi* and others; and yet, perhaps, not quite, for the colour, though at its best vying with that of *M. grandis*, say, is just the least little bit unstable. It occasionally fails to keep "that school-girl complexion," and takes on purplish tones; few species in the blue group are altogether immune from that degrading tendency.

M. violacea (K.W.) belongs to the group 'Robustae', and differs from *M. Wallichii* in having solitary flowers instead of cymes in the axils of the bracts, and from all the other species in its deeply-pinnate, Fern-like leaves. In its first year it produces an enormous crown of pale sea-green leaves encased in golden hairs of silken texture, barbed nevertheless. This leafy crown survives the winter under the snow. A huge, bloated, Carrot—but spongy as a senile Radish inside—plunges down through the loose meadow mould into the stony earth beneath, and the waters under the earth—three or four feet under, firmly anchoring the plant. When the snow has melted, the flowering stem erupts out of the woolly heart, and stretching itself, presently ends in a flower. As yet the stem is only about three feet high, but continuing to grow until checked by the October frosts, it ultimately stands six feet above ground. There are five or six petals of a deep violet colour, with a sheaf of golden anthers bobbing round the bristly, egg-shaped ovary, which is crowned by a long, columnar style. Bracts narrow, drooping; pedicels short, but lengthening and straightening in fruit; capsule large, opening by ten or twelve small canine teeth, exposing a series of narrow slits between the capsular ribs. Thus the whole, in bloom, forms a slim gold and green column of violet flowers, leaning over leafy balconies to nod to the passing insects.

On the Burmese side of the range, *M. violacea* is fairly common between 10,000 and 13,000 feet, the usual experience being to find a scattered colony of half-a-dozen plants growing on a steep alpine slope, whether gravel or meadow, and no others anywhere near. On the Tibetan side it is a rare plant, and it keeps clear of the limestone. It has the defect of its biennial comrades, and a slight impediment in its complexion, but when the worst has been said, *M. violacea* is a first-class plant.

Early in July, on the high and steep 'Lapponicum' moorland, at 13,000 feet, I found half-a-dozen plants of a pale, yellow-flowered *Meconopsis*, which at first sight looked unfamiliar, but which on closer inspection were seen to conform to *M. pseudointegrifolia*. Its slender gracefulness and chic flowers, however, earned for it the varietal name of *gracilis*. It was quite a rare plant, and we must have been right on the outer limit of its area. I collected *M. pseudointegrifolia* in Tibet in 1924, and it is fairly common in Yunnan, extending eastwards and northwards; the variety *gracilis* comes from an intermediate locality, and is the first yellow Poppy recorded from Burma.

Lastly, there is *Meconopsis calciphila*. Above 12,000 feet, and commoner on the limestone range, though overlapping also on to the granite,

there flowered in July a member of the section *Aculeatae*. It was a typical, prickly, blue Poppy, with the habit of *M. Prattii*, that is, a central stem bearing solitary flowers on axillary pedicels, longer or shorter, rarely if ever producing radical, one-flowered scapes in addition. The flower colour was a rather uncertain blue, dark or light, with golden anthers. Its affinities are with the Chinese members of the group, rather than with the Himalayan, since it always has five or six petals—but the leaves are entire. In this last respect it comes nearest to the Tibetan *M. Prainiana*, but it is not nearly such a tall plant, rarely exceeding eighteen inches, nor has it the prominent, elongated style of *M. Prainiana*. In the high alpine region it was very abundant, especially on the Tibetan side, where the limestone range

THE BERMUDA LILY.

THE Bermuda Easter Lily (*Lilium longiflorum* var. *eximium*, Baker) first reached Bermuda about 1872, probably from Europe, for it had been known on the Continent for some forty years previously. It is doubtless a native of the Liukiu or Loo-choo Archipelago, a chain of islands stretching from the south of Japan to Formosa, and strikingly similar to Bermuda in their equable though humid climate and calcareous soil. These islands are the native habitat of the Japanese trumpet Lily, *Lilium longiflorum*, Thunberg, to which the Bermuda Lily is closely related.

The first bulbs to reach Bermuda were grown in gardens in the historic capital, St. Georges,

In 1883, the Bermuda Lily first attracted attention in England. A fine spike was exhibited by Mr. G. F. Wilson, of Weybridge, at a meeting of the Royal Horticultural Society and was awarded a First Class Certificate.

Subsequent to that date, the Lily attained great popularity in the United States and in England, as numerous references to it in horticultural journals testify.

About the year 1900, however, a "peculiar sickness" became very prevalent in the Lily fields, and after that date the number of cases exported rapidly declined until before the war they reached a negligible quantity. Recent work carried on at the Department of Agriculture, Bermuda, has shown that the cause of the decline of the industry was one, if not two, virus diseases, strikingly similar to the well-

FIG. 245.—A FIELD OF THE BERMUDA LILY, IN BERMUDA.

was better developed; and its presence there was sufficient proof that the main divide lies almost out of reach of the monsoon. If not entirely confined to the limestone, *M. calciphila* is much more at home there. Unfortunately, it is not a species of much garden value, more because we already possess several good plants belonging to the group '*Aculeatae*' than because of any signal defect in *M. calciphila*. It just succeeded in being ordinary.

This concludes the list of Burmese *Meconopsis* as at present known, although I have little doubt there are other species lurking on the dim, distant frontier ranges. Which of them are likely to be successful introductions? Of the above, *M. violacea* promises best, and *M. Baileyi* var. *pratensis*, though less new, ought to succeed. We have ample seedlings of both. No doubt *M. rubra* is the best of all, and the seeds have germinated; but it is too like *M. impedita* to allow of optimistic forecasts as to its future. *F. Kingdon Ward.*

where their vigorous growth and the beauty of their flowers soon attracted attention. Their commercial possibilities were first realised by General Russell Hastings, formerly of Ohio, a retired Civil War veteran, who had made his home at the estate of Soncy, near Hamilton. He collected so many of the bulbs as possible and started the cultivation of Lily bulbs on a large scale. He soon discovered that the soil, temperature and humidity prevailing in Bermuda were admirably suited to its growth.

Entering into agreements with firms in New York and elsewhere, he found the business an extremely profitable one, and it was not long before others followed his lead, and the cultivation of the Lily was undertaken all over the islands.

The present trade name of the Lily, "*Lilium Harrisii*," was given to it by Mr. W. K. Harris, a well-known grower of Philadelphia, who received bulbs from Bermuda in 1876 from a Mrs. Thomas P. Sargent.

known "degeneration" diseases of Potatoes—Leaf-roll and Mosaic. It has been shown that one of these diseases is conveyed from plant to plant by an aphid. The symptoms on the plant are very marked, bringing about an extreme dwarfing of both plant and bulb. The greenhouse-men found that the bulbs produced dwarfed or distorted plants which failed to flower properly, hence they gave up growing the Bermuda bulbs and welcomed the formosums, giganteums and multiflorums, which were coming in large quantities from Japan and the Azores.

After the conclusion of the war, however, the more progressive of the Lily growers in Bermuda made an attempt to resuscitate the industry by the improvement of their types of bulb and by combating disease. On more than one occasion in the past there had been large importations of Japanese Lilies of poor type, and these had become mixed with the Bermuda stocks. It is possible that at the same time

the virus diseases were introduced, for these have been found in Japanese strains of *Lilium longiflorum*. The growers, therefore, selected vigorous bulbs of good shape and true to type and propagated vegetatively from these only. By such means they were able to secure remarkably uniform fields in a few years.

The fresh light thrown on the diseases of the Lily by the investigations carried on by the Bermuda Department of Agriculture enabled control measures to be instituted which soon resulted in their practical elimination. For the last three years the fields have been subject to a very careful official inspection which takes place about flowering time and has as its object the elimination of all plants which do not agree with the typical so-called *Lilium "Harrisii,"* or which are in any way diseased or of poor growth. The bulbs are also subjected to a thorough inspection at the packing sheds after they are lifted.

The results of these measures have been very gratifying. The fields (Fig. 245) are now of remarkable uniformity, disease is practically absent, and the number of cases exported has risen from 1,604 in 1922 to over 6,000 in 1927.

There are indications that the Bermuda Easter Lily is again finding its way into popular favour in England. Many testimonials as to its high quality have been received by the Department. Amongst these is a letter, dated April 19, 1927, from Dr. A. W. Hill, Director of Kew Gardens, in which he refers to a display of Lilies grown from Bermuda bulbs in the Kew greenhouses—"The bulbs of the Bermuda Lilies which were sent over to Kew are making a magnificent display of flower. The plants are about five feet high, and each one carries some seven to nine flowers, and they are perfectly healthy and quite the best Lilies we have ever had in cultivation here. We have had them labelled that they came from Bermuda."

The period of growth of the Lily in Bermuda is from October to July. Propagation is entirely by scales and bulbils, mainly the former. The bulbs are usually packed in coral sand but several recent consignments have been made in peat moss. Shipments may be received from August onwards.

The bulbs should be potted up in a rich compost, free from fresh manure, and when the soil has been watered thoroughly they should be placed in a dark, cool place, protected from frost. Under such conditions the bulbs will root readily. When the shoots are about two inches high, the pots should be moved to a greenhouse with a temperature of about 65° to 70°. The plants should receive an abundance of air, and be watered freely on bright mornings. It will require approximately thirteen weeks from the time the plants are brought into the house until flowering time.

The chief distinguishing features of the Bermuda Lily are the abundance and size of the flowers, which are of a pure, glistening white, either horizontal or slightly drooping, and have the perianth segments markedly reflexed. The habit of the plant is pyramidal, the leaves being slightly reflexed and abruptly pointed. The bulbs are of a rich golden-yellow with tapering scales. *Lawrence Ogilvie, M.Sc. (Cantab.), Department of Agriculture, Bermuda.*

CHILI AND THE ANDES.

IV.—ON THE WAY.

It was rather surprising on leaving the intense heat of Panama and running south to the equator, to find that the weather instead of becoming warmer, grew steadily cooler. The whole run south, down the Peruvian and North Chilean coast to Valparaiso, was rather cool and mostly sunless. Even while passing through the tropics one was glad of an overcoat and grateful for a big coal fire in the smoking room.

The climate of this Peruvian and North Chilean coast is governed by the great Humboldt

current which, sweeping up from South Polar regions, keeps the temperature low, and reduces rainfall to a minimum. The coast is almost continually overhung by a great grey canopy of cloud, yet droughts of twenty and thirty years' duration are not uncommon in some districts. *i.e.*, complete droughts when not a single shower of rain falls. Except where occasional rivers run down from the Andes this coast belt is utterly barren desert, almost without a vestige of vegetation of any kind. It is curious therefore to reflect that this completely sterile country is, potentially, one of the world's most fertile regions. There are vast deposits of nitrate and there are the Guano Islands. Owing to the dryness of the climate neither of these fertilisers can be used as such on the spot, but, on the contrary, it is due to the dryness that the guano can accumulate, and that the nitrate was not long ago dissolved and washed away. The export of these fertilisers is, of course, an important business.

We put in for an hour or two at the little Peruvian port town of Payta, but were unable to go ashore. It looked a dreary little place set on a narrow, barren shore, with dun-coloured, desert mountains rising immediately behind, and not a sign of vegetation to be seen. Another day's run brought us to Callao, the port town for Lima.

For sheer, shabby beastliness, Callao must surely be hard to beat. We did not, I confess, make a systematic hunt for its beauty spots, but we passed through the town in two directions and the impression gained was of corrugated iron, rusted and corroded; of peeled and blistered paint work half hidden by dust and grime; and dust and dirty paper blowing about the uncleansed streets. So we hurried out to Lima, eight miles, by train. Lima, "City of the Kings," built by the terrible Pizarro, should, with its name and its romantic history, be a far more beautiful and interesting city than it is. But frequent alternate earthquakes and revolutions do not tend to the preservation of ancient historic monuments. Yet Lima is a fine city, with well laid out squares and public gardens and much really splendid street planting. The planting of open spaces in South American towns is altogether admirable, and makes one realise how deplorable is the state of most of London's smaller "open spaces," which are not open at all, but railed in and locked, and hedged with banks of stricken Privet. The beds, for the most part, contain little but rubbishy shrubs and sickly survivals of Victorian bedding, badly done. Almost the only good feature of London's squares is the Plane trees. London's larger parks, Hyde, Regent's, Battersea—have, of course, long been famous for their excellence and magnificence, and every year they seem to gain in beauty and horticultural interest, but a visit to a few South American towns and a study of their lesser public plantings make one realise as never before what a pitiful disgrace many of the London squares are.

We visited the Botanic Gardens at Lima, which combine the functions of public park, botanic gardens and zoo. The botanical interest lay chiefly in the trees, splendid Palms, large specimens of several species of *Araucaria*—mostly wrongly labelled—gigantic tree *Ficus*, *Jacarandas*, etc.

Late in the afternoon we ran out by car to see the ruins of the ancient Inca city of Pachacamac, a twenty-five-mile run, first through the pretty suburb of Miraflores, where *Bougainvilleas* were splendid on many of the houses, both the purple sort and a brilliant Indian-red variety, and so on through irrigated agricultural land, Cotton, Maize, Vines, Potatoes, etc. Then a brief zone of wild land without irrigation, where a thin, dust-coloured vegetation barely clothed the dun-coloured hills. The last ten or fifteen miles of our journey lay through sheer, unmitigated desert. Here the track lay straight and narrow along a level belt of deep, soft sand. Half-a-mile to our right Pacific breakers thundered dully upon the featureless shore, spouting slowly up in gigantic Mushrooms of white foam. Half-a-mile inland the desert rose abruptly in a range of low, fawn-coloured

mountains. So far as the eye could reach there was not a sign of vegetation of any kind, unless some strange, dark patches far up on the hills were colonies of some xerophytic plant. The only sign of life of any kind was a company of a dozen or so pelicans in heavy grotesque flight, wheeling and patrolling in perfect formation up and down the coast.

At one point we passed through a half-mile zone of pungent stench, and found that we were passing—down wind—a guano island which lay some ten or fifteen miles out to sea. At last we came to a little farm oasis, with fruit trees and Palms and Prickly Pears, and just beyond this was the ruined city of Pachacamac. It stands on steeply hilly ground. Its walls of sunbaked mud stand solid and roofless. For an hour or two we wandered and explored, enchanted by this romantic place, tracing its sand-drowned streets, its silent houses, temples and tombs. Quantities of bones lay about, fragments of human skulls, Inca pottery, mummy wrappings still showing traces of coloured pattern, even human hair, coarse and reddish-coloured. One great charm of exploring these strange ruins was that one was utterly alone, and could wander where one would, unworried by any tiresome professional guide.

The ruins of Pachacamac yielded one item of botanical interest, a queer Bromeliaceous plant which sat and lay about on the burning sand, in the great open space of the Temple of the Sun, in the streets, sometimes on the walls, singly or in colonies. It was roughly like the top of a Pineapple, dry and steely-grey, with now and then a flower spike pushing forth, a foot or two high, fleshy, clothed in sheathing, orange scales, and with protruding magenta blossoms. Sitting and lying about is the only way to describe the habit of the plant. It had no roots to speak of, just a few little, inch-long, wiry rootlets, too feebly ineffectual, one would imagine, to act as anchors or feeders. It was not a case of digging the plant up; one just picked it up. Three young ones have been carried about in my baggage for over two months, waiting for a suitable box to travel to England in, and they seem none the worse.

Apparently a few xerophytic species of plants exist in this practically rainless region, being so constructed and adapted that they can absorb enough moisture for their needs from the mists which prevail there.

Our second day in Lima yielded a plant of considerable horticultural promise. We were motoring out to Miraflores, and had stopped to examine some roadside weed—*Argemone mexicana*, I think it was—when we noticed in a field, fallow after a crop of Maize, hundreds of flowers which looked, superficially, like very large and splendid *Sternbergias*. The plant grew about twelve to eighteen inches high and the great, leafless, goblet flowers of clear, pure gold were really magnificent. I fancy it belongs to *Amaryllidaceae*. We had only one trowel between us, but, fortunately, the soil was rich and moist, and the bulbs not deep. We were already late for a luncheon appointment, but for ten minutes we worked like fiends, digging with the trowel, a walking stick and with fingers. We arrived not only desperately late for lunch, but caked with rich, black loam, and our pockets bulging with bulbs and bristling with great golden blossoms. One solitary specimen we found with a splendid orange flower. We dug it up, of course, but the flower got broken off and the bulb mixed with the general stock of C.E. No. 1. Later, we saw a whole field full of nothing but this orange-flowered variety, but we saw it from a motor-bus and it was impossible to stop and collect it.

As we left Callao we made a find, which, if anything could, might make me tone down the hard things I have said of this place. In a bed in a public garden close to the quay we found plants of that splendid orange *Cosmea* which we had seen, but failed to secure at Panama. The plants, moreover, were carrying ripe seeds, a little of which we were able to steal but—owing to the police, and in view of things we had heard of Peruvian prisons—not very much! *Clarence Elliott.*

THE DINGLE, QUARRY PARK, SHREWSBURY.

IDEAL GARDENS AND PLANT LORE.

THE GARDEN OF THE MADONNA.

(Continued from page 491.)

So vast is the number of flowers and plants associated with the name of the Virgin Mary that one finds it difficult to decide how they may best be arranged. One garden-lover would perhaps wish them to be named in the order of blossoming, beginning, we will say, with the Snowdrop and ending with the Christmas Rose. Another would like them set out in relation to the festivals of the Church, such as the Annunciation, Assumption or Conception. For a third, the arrangement which would give greatest pleasure would be the one which represents the wardrobe of Madonna—her nightcap, garters, shoes and stockings, smock, mantle, ruffles and ribands, with such ornaments as signet, eardrops and purse. A fourth would like the plants named alphabetically. Yet another, with a weakness for classification and system, would wish the plants to be arranged according to their botanical orders, beginning with the Ranunculaceae and ending with Grasses and Ferns.

On the whole, the latter appears to be the most satisfactory arrangement, and we will therefore take any well-known British Flora or the *London Catalogue* as the basis, adding or omitting as circumstances may require. Our beds may then be laid out as they are in a botanical garden, their size being adapted to the site and the number of plants devoted to the Virgin which the different Orders contain.

Though not directly named after the Madonna, the Hellebore or Christmas Rose can hardly be omitted, seeing that it is intimately associated with the birthday of her Son, and bears such names as Christ's Bloom, Wort, Flower and Herb. This will be the first flower to greet us, and may therefore well be planted near the bower which is covered with the leafless branches of its nearest relative, the Clematis. The same bed or border will contain specimens of the Wood Anemone, known in the west as Lady's Nightcap; and Adonis Flower or Pheasant's Eye (*A. autumnalis*), which is known in Württemberg as Marienröschen, and in Silesia and Swabia as St. Mariablom and Marienröslin. For particulars respecting the plant-lore of this flower we may refer to the papers which have already appeared in these columns. The Columbine is another of the flowers belonging to this Order which has been dedicated to Mary, on account of the peculiar shape of the blossom. In Cornwall it is named Lady's Slipper, in East Anglia Lady's Shoes, while in Germany it is Lady's Glove (*Frauenhandschuh*), a name which the peasantry of Northants apply to the Bird's-foot Trefoil (*Lotus corniculatus*).

Many years ago I discovered that the term Lady's Pincushion was used in South Devon for the Yellow Fumitory (*Corydalis lutea*). If we turn to the dictionaries of plant names, we shall find that several other plants bear this name, including the well-known Thrift, a garden Scabious, a Saxifrage, and the Lungwort (*Pulmonaria*). The white anthers of the Scabious and the white spots of the Lungwort suggest the name, as does also the tufted, cushiony growth of the Sea Thrift (*Armeria*). A rock cress (*Arabis albidia*) is known in Lincolnshire as Lady's Cushion.

Thus we come to the Cruciferae, and at once remember the Lady's Smock (*Cardamine*), a name which is applied also to the Wild Convolvulus, and more rarely to the Arum. This name seems to be absent from German plant lore relating to the Virgin, a fact which suggests that one might profitably compare the popular names of plants in western Europe and Great Britain, with a view to ascertaining what light they throw on the origin or development of different religious systems. Italy is naturally peculiarly rich in Madonna plant lore. We shall find as we proceed that a large proportion of the plants which bear the name of Mary in England are similarly named in many parts of Germany, whilst others are added to our list. Among Crucifers, for example, the Wallflower is known as Mariastengel in Appenzell,

though it bears no corresponding name in this country.

Before passing from this Order we must draw attention to another unusual name for the Lady's Smock. In Yorkshire it is called the Lady's Milk Sile. "In the north to sile milk is to strain it, and the tin sieve, in form like the wide part of a funnel, is called a *milk-sile*. It is possible that the name of the flower is derived from a fancied resemblance in shape to the milk-strainer." There is, however, another explanation. It is well-known that in popular language the same name is often transferred from one plant to another. Now the Lungwort (*Pulmonaria*) is in Cheshire known as Lady's Milk Sile, the word *sile* or *soil* meaning in this case a spot or stain. The name thus has reference to the legend which is also associated with the Milk Thistle, that drops of the Virgin's milk fell on the leaves, and in this way caused the white spots which are still seen on their surface.

So far as my memory serves, we have no other plants in this Order for our Madonna Garden, nor do we find any English plant among the Mignonettes, Rock Roses or Violets to place here, though Germany gives the same name to the Sweet Violet as to the Wallflower. We shall need a little space for the family of Pinks (*Caryophyllaceae*). In Germany the Bladder Campion is Marienrädchen, though not devoted to the Virgin in England. This plant (as well as some of the related forms) is also known as Marienrose, or Röschen, a name which is applied to the Adonis Flower, Sweet Briar, and even to a Verbascum; reminding us of the fact that we call the Mullein, Virgin Mary's Candle and Our Lady's Foxglove. There is a species of Pink (*Dianthus deltoides*) which we call the Maiden Pink, and the term maiden may in this case be the equivalent of Virgin, seeing that in some parts of Germany the same plant is named both Marienröpfen and Jungfernelke, the latter being the exact equivalent of our own name. The name Lady's Lint is used in Devonshire when speaking of the Stichwort (*Stellaria*), "probably from the white threads in the centre of the stalks," as Britten suggests. In Germany the terms Jungferngras and Jungfrauengras are applied to the same plant. In Hereford we find the picturesque and suggestive epithet of Lady's White Petticoat.

In Germany the name of the Madonna is intimately associated with the Perforate St. John's Wort. Together with such names as Frauen-Kraut and Unser Frauen Bettstroh (which is our name for Galium) we also find in old records Sunten Marienvlas, or St. Mary's Flax, with a Dutch atmosphere. The Wood-Sorrel (*Oxalidaceae*) has several names belonging to the Virgin. In Dumfriesshire it is called Lady's Cakes, in Perthshire Lady's Clover, and in Clackmannan Lady's Meat.

The first of the Legumes which claims a place in our list is the Broom. We place it here, not because it bears the name of the Virgin, but on account of its legendary associations. It was the crackling of the seed-pods of the Broom which drew the attention of Herod's soldiers to the spot where the fugitives were hidden, and so drew down upon it the maledictions of the Holy Mother. According to the Bolognese, however, it was the Lupin which performed this ungracious service, and we must therefore place them side by side. We note, however, that Frauenschüchel is a German name for the Broom, and this helps to redeem its character. The Bird's-foot Trefoil which belongs to this Order (*Leguminosae*) has several names which entitle it to a place here. The German forms include Frauenfingerkraut, Frauenschühl with several dialectical variants, Frauen Schlüssel, and the like. These are matched by the English Lady's Fingers, Lady's Glove, Lady's Slipper and Lady's Shoes and Stockings. The first of these names is also given to other members of the Order, including the Anthyllis, a Vetchling (*Lathyrus pratensis*), and the Laburnum, while other plants bearing the title will be mentioned in our notice of later Orders. In Germany a Bean is devoted to the Virgin and known as Marienblume, St. Mariabohne and Jungfernbohne. The latter sometimes occurs as Muttergottesstockbohne!

Passing now to the Rosaceae, we find the

Dog Rose (*Rosa canina*) called Mariendorn in east Prussia; another name is Jungtornrose, while the Sweet Briar is Frauendorn, Frauenrose, Mariendorn, Marienröslein, Marie-hagrose and Maria-windeltrock, to mention no others. It is curious to note that the Bramble is called in Roxburghshire Lady's Garters, a name which is more usually reserved for the striped Ribbon Grass (*Phalaris*). The Strawberry, as already noted, belongs to the Virgin; mothers should therefore refrain from eating them, since by so doing they rob the rightful owner, and risk the expulsion of their children from heaven; A well-known plant belonging to this Order is the Alchemilla, which bears the name of Our Lady's Mantle on account of the shape of the leaves. The alpine Lady's Mantle is a pleasing addition to the rock garden. In Mexico this name is applied to an Ipomaea, "the azure blossoms of which are four to five inches across, and set so close together that hardly a leaf is to be seen, and the whole plant resembles a blue cloak." The Mexican or Spanish name is Manto de la Virgin. The Germans, like ourselves, devote the Alchemilla to the Madonna, naming it Marienkraut, Marienmantel, Unser Frauen Mantel, Unser lieben Frauen Nachtmantel, with many other variants. It is in certain parts known also as Muttergottesmäntelchen.

The mention of the latter name reminds us that quite a number of plants have been dedicated to the Mother of God, as the Virgin is called in different parts of Germany. Thus we have Muttergottesbettstroh, our Lady's Bestraw (*Galium verum*); Muttergottesgläschen, not, as with us, for a Campanula, but for the Bindweed (*Convolvulus arvensis*). A Chrysanthemum (*C. tanacetum*, Kar.) is the Virgin's Rod or Muttergottesruthe; the Quaking Grass (*Briza media*), which is called in Cambridgeshire Lady's Hair, is her tears—Muttergottesthränen.

One other plant may be mentioned, because it is not a Madonna Flower with us. This is the pretty Centaury (*Erythraea Centaurium*, L.) which is named Muttergotteschut in St. Gallen. Chrut or Crut, as it is sometimes spelt, in old herbals and other works, is the equivalent of *kraut*, a vegetable, herb or plant, so the Centaury is the Virgin Mary's herb. Here we must rest, in the hope of being able to complete the list in our next article. *Hildegard Friend.*

(To be concluded.)

MESEMBRYANTHEMUM.

(Continued from p. 490.)

12.—GLOTTIPHYLLUM, HAW.

21. *G. latum*, N. E. Br., in *The Gardeners' Chronicle*, 1921, Vol. LXX, p. 327 (Fig. 246).—Growths more or less pressed upon the ground. Leaves in two ranks, straight or slightly curved downwards edgewise, those of the smaller form about $1\frac{1}{2}$ – $2\frac{1}{2}$ inches long, and of the larger form $2\frac{1}{2}$ – $4\frac{1}{2}$ inches long, 6–9 lines broad and 2–4 lines thick, strap-shaped and of about equal breadth throughout, broadly rounded or subtruncate at the apex, with or without a short mucronate point at the end of the upper edge, flat or nearly so on the face, without any pustule at the base, more or less convex on the back, smooth, glabrous, soft and pulpy, uniformly green, not at all glaucous, shining. Pedicels 3–10 lines long, and in fruit—where left uncovered by the bases of the leaves—up to an inch long, 3-angled, $2\frac{1}{2}$ lines thick, glabrous. Calyx subequally 4-lobed; lobes 4–6 lines long, ovate, obtuse or subacute, three of them acutely keeled on the back. Corolla, $1\frac{1}{2}$ – $2\frac{1}{2}$ inches in diameter, expanding only in bright sunshine in the morning and closing in the afternoon, about 5 p.m., not fragrant; petals numerous, in 2 series, 11–13 lines long, $\frac{3}{4}$ –1 line broad, linear, acute, bright yellow, tinged with coppery or reddish on the back at the tips. Stamens very numerous, 3– $3\frac{1}{2}$ lines long, bright deep yellow; filaments not bearded. Stigmas 9–10, radiating, $1\frac{1}{2}$ line long, stoutly plumose, acute,

greenish-yellow. Ovary partly superior, convex on the top, 9-10-celled. Capsule broadly obconic, with a raised, dome-shaped top, with 8-10 valves and cells, 6-7 lines in diameter when closed and 10-12 lines in diameter when expanded; valves pallid within; expanding keels dark brown, with pallid, awn-like tips; cell-wings brown; tubercle ochreous. Seeds $\frac{1}{2}$ line in diameter, compressed-ellipsoid, with a small nipple at one end, nearly smooth, being only very minutely tuberculate as seen under a strong lens, brown.

G. obliquum, N. E. Br., in *The Gardeners' Chronicle*, 1921, Vol. LXX, p. 336. *Mesembryanthemum latum*, Haw., *Obs.*, p. 186 (1795). *Misc. Nat.*, p. 32, *Syn. Pl. Succ.*, p. 220, and *Rev. Pl. Succ.*, p. 98, founded upon *M. folio linguiformi latiore* Dillen., *Hort. Elth.*, p. 236, t. 184, f. 225. *M. latum* var. *breve*, Haw., *Rev. Pl. Succ.*, p. 99; N. E. Br., in *Journ. Linn. Soc. Bot.*, Vol. XLV, p. 69. *M. linguaeforme*, Haw., *Obs.*, p. 182 (1795), *Misc. Nat.*, p. 33, *Syn. Pl. Succ.*, p. 221, and *Rev. Pl. Succ.*, p. 97; *Lodd., Bot. Cab.*, t. 1307, and vars. *suberuciatum*, *prostratum* and *assurgens*, Haw. *Rev. Pl. Succ.*, p. 98. *M. linguiforme* var. *g.*, Linn. *Sp. Pl.*, ed. 1. p. 488, founded upon *M. folio linguiformi angustiore* Dillen. *Hort. Elth.* p. 237, t. 185, f. 226. *M. linguiforme* var. *latum*, Salm Dyck, *Mes.*, §8, f. 8B. *M. obliquum*, Willd., *Sp. Pl.*, Vol. II, p. 1027 (1799), also founded upon f. 226 in Dillen. *Hort. Elth.*; N. E. Br. in *Journ. Linn. Soc. Bot.*, Vol. XLV, p. 71. *M. medium*, Haw., *Suppl. Pl. Succ.*, p. 88 (1819), and *Rev. Pl. Succ.*, p. 95; N. E. Br. in *Journ. Linn. Soc. Bot.*, Vol. XLV, p. 132. *M. adscendens*, Salm Dyck, *Mes.* §8, f. 4, and perhaps of Haworth, see note below. *M. linguiforme* vars. *adscendens* and *obliquum*, Berger, *Mes. und Port.* p. 241. Probably *Ficoides africana* acaulos, folius latissimis, etc., Bradley, *History of Succulent Plants*, Decade III, p. 6, f. 24 (1725) should be referred to this species.

Var. cultratum N. E. Br. (Fig. 246 F-G).—Leaves more or less curved downwards, edgeways, with the tips slightly upcurved. Pedicels about an inch long. Corolla about 2 inches in diameter and like that of the type.

G. cultratum, N. E. Br., in *The Gardeners' Chronicle*, 1921, Vol. LXX, p. 336. *Mesembryanthemum cultratum*, Salm Dyck, *Obs. Bot.*, p. 7 (1820) and *Mes.* §8, f. 5; Haw., *Rev. Pl. Succ.*, p. 95. *M. depressum*, Salm Dyck, *Mes.*, §8, f. 7 (not of Haworth, nor of *Bot. Mag.*, t. 1866). *M. linguaeforme*, Salm Dyck, *Mes.*, §8, f. 8. *M. longum* and var. *flaccidum*, Haw., *Syn. Pl. Succ.* pp. 221-222 (1812), and *Rev. Pl. Succ.*, p. 96, excluding synonymy (but not *M. longum* of Haw. *Obs.*, 177, which was founded upon a Dillenian plant with ascending leaves, whilst Haworth describes later a plant with leaves pressed upon the ground). *M. lucidum*, Haw., *Suppl. Pl. Succ.*, p. 89, and *Rev. Pl. Succ.*, p. 95, excluding synonymy, not of Miller. *M. longum* var. *declive*, Salm Dyck, *Mes.*, §8, f. 9B, not of Haworth. *M. linguiforme*, vars. *declive*, *depressum* and *cultratum*, Berger, *Mes. und Port.*, p. 240.

Riversdale Division: On hills near Riversdale, 700 feet alt.; Muir 3874! 3875! Mossel Bay Division, near the Little Brak River, Burchell. This was in cultivation before 1732.

This species varies considerably, and much confusion of names has been created by Haworth, who first wrongly described it as being *M. linguiforme*, Linn., and then described various slight forms of it as species and varieties, in which others have followed him. Salm Dyck made further confusion by figuring this species and its variety under several different names. I have again studied all Haworth's descriptions with close attention to detail and compared them with all the drawings and published figures relating to them at Kew, and this comparison, with the aid of living plants and some information about them in their native country received from Dr. J. Muir, has enabled me to alter my former view that *G. latum*, *G. obliquum*, and *G. cultratum* were three distinct species, and also to feel confident that the synonymy as here given is (at least, for the greater part) correct. With reference to *M. adscendens*, Haw., *Syn. Pl. Succ.*, p. 220 (1812), and *Rev.*

Pl. Succ., p. 96, however, there is some difficulty in understanding what plant Haworth means. His description of it is as follows:—"Leaves ascending, broadly tongue-shaped, very obtuse, green. Flowers pedunculate," and in another description "peduncles longer (than in *M. latum*)." And he adds, "The leaves are more ascending and paler than in the last (i.e., *M. latum*), and the peduncles longer. If the next species but three (i.e., *M. longum*) is not the *M. folio linguiforme longiore* of Dillenius, this may be it; but, if so, he has delineated the leaves too long." This description seems more to accord with *G. longum* than with *G. latum*, and in *Rev. Pl. Succ.*, p. 96, he remarks, "Probably a variety of the former" (i.e., *M. lucidum*, Haw., which is *G. longum*). There is, however, a drawing at Kew, undated, but probably made somewhere about 1820, labelled "*Mesemb. adscendens*, Haw.," which repre-

FIG. 246.—GLOTTIPHYLLUM LATUM.

A.—E.—Part of a growth and tips of leaves of the type, natural size. B.—E.—Being from one plant. F.—G.—Part of growth, reduced, and tip of leaf, natural size, of var. *cultratum* (see text). Flowers pedicellate.

sents a plant of *G. latum*, with leaves spreading near the ground, and is very like that which Salm Dyck has figured as *M. adscendens*, except that the pedicels and calyx are not represented as being tuberculate, from which character I have no doubt that Salm Dyck's figure §8, f. 4 represents *M. latum* var. *b* Haw., *Misc. Nat.*, p. 33=*M. latum* var. *breve*, Haw., *Rev. Pl. Succ.*, p. 99. But these tubercles I believe to be due to the attack of some mite; they are not normal plant-tubercles and occur but rarely in my experience. I do not remember to have seen them on a *Glottiphyllum*, but I have on other genera, where also they are not normal structures.

If this drawing at Kew and Salm Dyck's figure are correctly named, then I would suggest that Haworth described *M. adscendens* from a plant of *G. latum* that had been grown under glass and not fully exposed to the sun. This view is rendered probable by plants of *G. latum* that I possess, which, as I write (January, 1927), have ascending leaves, yet when received early in 1926 the leaves were more or less pressed down edgeways near to the ground, not ascending; the alteration to an ascending position being due to the very unfavourable condition of an absence of direct sunlight during the three winter months.

Several plants of this species were sent to me by Dr. J. Muir, some of the smaller and harder type and some of the softer and more juicy form, of which remarks have already been made under the genus. Under the unnatural conditions in which I have to cultivate them, these plants have much altered in appearance, and if placed in the hands of most cultivators of succulents, without knowledge of their origin, would probably be thought to belong to two or three species, or at least varieties. One of them, which, when received, had nearly straight leaves spreading right and left nearly in a line (as in Fig. 246, A), after a time developed leaves curved downwards with slightly upcurved tips, exactly as represented by Salm Dyck for *M. cultratum*. In January, 1927, this put forth a pair of apparently straight leaves, but whether these will remain straight or eventually become curved like the others is at present unknown. This specimen is illustrated by Fig. 246, F and G, and clearly demonstrates that *G. cultratum* is not a distinct species, but merely a variation of *G. latum*, just as I now find that *G. obliquum* is merely a smaller form of this species, they are merely individual forms of one species, for there is no difference in their flowers. It is strange that Salm Dyck figures this variety *cultratum* under no less than four different names, for the four figures quoted above under that variety are certainly only individual forms of one plant and might even have been made from the same specimen in different years. The question arises, is this a variation that is due to cultivation and not found in the wild state? For having seen one of my imported plants change under my own eye from the straight-leaved *G. latum* to the curved-leaved variety *cultratum*, I wrote to Dr. Muir for information as to whether *G. cultratum* occurred with *G. latum* in its native habitat. He very kindly made a journey to the locality where it grows wild, and writes concerning it:—"I examined several hundreds of plants in the localities of my 3874 and 3875. Please note that in nature not one showed any evidence of the cultrate form which is evidently the sybaritic cultivated London or Salm Dyckian form of *G. latum*." This would seem to be conclusive evidence that the two forms are merely conditional variations of the same individual under cultivation only, and so, for garden purposes, the varietal name *cultratum* may be retained. If further proof is needed that *G. latum* and *G. cultratum* are one species, I may mention that at Kew there is an original drawing dated "Dec. 2, 1823" made from a plant received from Prince Salm Dyck in 1823 under the name of "*M. cultratum*," which represents the plant as having nearly straight leaves, just as my plant (mentioned above) had when received from South Africa.

Dr. Muir informs me that in their native localities this and other species will "stand frost well. But when they are brought into a garden (meaning in South Africa in the region where they grow wild) and get more water they swell up, become bloated and very luxuriant but invariably blacken and die when frost comes and catches them in this abnormally luxuriant state." This information indicates that these plants should receive very little water during the winter, in Europe, if it is desired to keep the more choice and delicate species alive.

22. *G. depressum*, N. E. Br., in *The Gardeners' Chronicle*, 1921, Vol. LXX, p. 327 (Fig. 247).—Growths pressed upon or directed towards the ground. Leaves 2-ranked, apparently about 2-2½ inches long and 7-8 lines

broad, and of nearly equal breadth throughout, nearly horizontally spreading or slightly sloping downward and slightly curved upwards edgewise at the tips, strap-shaped, obtusely rounded at the apex, with a short point directed forwards at the upper edge, pale green (in the original drawing the green is much paler than in the reproduction of it). Flowers sessile. Calyx unequally 4-lobed; three of the lobes keeled and the keel minutely ciliate. Corolla cup-shaped, 2 inches or more in diameter, expanding in sunshine only, not in cloudy or dull weather; petals in 2 series, acute, yellow, with a red midline and the apex itself frequently red on the back. Stamens short, yellow. Stigmas 10, very short, ovate-lanceolate (probably plumose), incurved, yellowish. Capsule depressed, with 10 ridges on the top and 10 cells.

Mesembryanthemum depressum, Haw., *Misc. Nat.*, p. 33 (1803), *Synop. Pl. Succ.*, p. 221, and *Rev. Pl. Succ.*, p. 99. *Bot. Mag.*, t. 1866, not of Salm Dyck. *M. rufescens*, Haw., *Syn. Pl. Succ.*, p. 221 (1812), and *Suppl. Pl. Succ.*, p. 89 (1819). *M. longum* var. *declive*, Haw., *Rev. Pl. Succ.*, p. 96 (1821). *M. linguaeforme* var. *rufescens*, Haw., *Rev. Pl. Succ.*, p. 98. *M. linguiforme* var. *flaccidum*, Berger, *Mes. und Port.*, p. 240.

South Africa: Locality and collector unknown. Cultivated by Haworth in 1795.

FIG. 247.—GLOTTIPHYLLUM DEPRESSUM.

Apical part of leaves, natural size; adapted from the *Botanical Magazine*. Flowers sessile.

This species is unknown to me, and the above is compiled partly from the original description of Haworth and partly from the figure in the *Botanical Magazine* which accurately agrees with Haworth's description, and from which I have adapted Fig. 247.

Haworth, however (*Rev. Pl. Succ.*, p. 96), wrongly refers the figure in *Bot. Mag.*, t. 1866, to his *Mesembryanthemum longum* var. *flaccidum*, which was founded upon a very different species with pedicellate flowers (see *G. latum* var. *cultratum*, and under *G. longum*), and I think it probable that Haworth intended to quote the *Bot. Mag.* figure under *M. longum* var. *declive*, which he places after var. *flaccidum*, and which has sessile flowers and according to description otherwise agrees with *G. depressum*, but by some accident he entered the quotation in the wrong place.

Haworth also wrongly quotes (*Syn. Pl. Succ.*, p. 221) Fig. 226 of Dillenius, *Hort. Elth.*, as belonging to *G. depressum*. But the Dillenian Figure has pedicellate flowers and belongs to *G. latum*, N. E. Br., which see.

I believe *M. rufescens*, Haw., should be referred to this species. There is no figure of it at Kew, and it is only known from Haworth's description, which in the sessile flowers and other characters stated seems to accord with *G. depressum*. The rufescent colour of the leaves mentioned by Haworth is not a specific character, but was doubtless due to some cultural cause, N. E. Brown.

(To be continued.)

THE LAW RELATING TO FIXTURES.

THE subject of what may be conveniently termed the law relating to fixtures, is one with which every gardener who hires the land he occupies and every landlord who lets the land is vitally concerned, and one with which they should both be acquainted.

The old general rule with regard to fixtures was that anything which became "fixed to the land," belonged to the owner of the soil, whether he had paid for it and put it up or whether it had been put there or "fixed" at the expense of the tenant or someone else. This rule, as has been pointed out in previous articles, has been so greatly relaxed as to be almost the exception in the case of land occupied and cultivated by certain classes of tenants, such as land occupied and cultivated as a market garden or an allotment or allotment garden. In the case of land not coming under any special statutory provision, as, for example, the Allotments Act of 1922, however, the general rule, in its somewhat modified present form, must be applied, and it is this class of case with which we are about to deal.

Taking the general rule as being that everything fixed to land by the tenant becomes the property of the owner of the soil, we must discover what exceptions to the rule the law now allows, and by what means things placed upon the land by the tenant during the tenancy become fixtures, and what do not.

The first great exception to the general rule that everything affixed to the land by the tenant becomes the property of the landlord, is to be found in what is known as "contrary agreement," that is, if it has been put there—supposing it is a building, or if it has been planted—supposing it is a tree or the like, with the consent of the landlord and under an agreement between the landlord and the tenant, by which the latter is entitled to remove it at the end of the term of his tenancy. This agreement may be found in the lease of the land in question, or it may be a collateral agreement. In any case where it is contemplated making considerable fixtures, such an agreement should, if possible, be obtained for the benefit of the tenant before he goes to any expense in carrying out some improvement to the land which can be considered a fixture.

Apart from agreement, another exception to the general rule occurs where the fixture in question, although it may be standing on the land, cannot be said to be actually attached to it. Thus, any structures which are merely resting on the ground or have become embedded in it as a result of their own weight only, will not be considered landlord's fixtures and can be taken away by the tenant whether he has entered into an agreement entitling him to remove buildings he has erected or not. With regard to hurdles and fences it has been held by the Courts that posts and rails put up by a tenant were not fixtures, nor were wood and iron hurdles which were moved about from time to time, although in this case it was said that if they were put up as a permanent fence they would be considered fixtures.

TRADE FIXTURES.

The next exception to the general rules comes under the heading of a "trade fixture," and the rule here is that anything which has been put up on the land by the tenant for the purpose of his trade or agriculture, he is allowed to remove during his tenancy without the consent of the owner of the land. These are generally known as tenant's fixtures, for whereas in the other exceptions there has either been an agreement that the things concerned shall not be considered fixtures at all, or else they are not true fixtures, in this case they are true fixtures, but the law allows the tenant to claim them, even though he has not obtained the consent of his landlord to their removal.

In cases which have been before the Courts on this point, it has been held that a greenhouse and a hothouse erected by a market gardener or a nurseryman for the purpose of his trade, were removable by him as trade fixtures; on the other hand, it has been held that a conservatory which was not built for the purpose of trade,

could not be taken away by the tenant as a trade fixture, nor was a tenant allowed to claim a greenhouse in a private garden, or a boiler built into the brickwork of the greenhouse. The pipes of the heating apparatus fixed to the boiler were, however, considered removable.

Apart from buildings, trees and plants may become fixtures and claimable by the landlord at the end of the tenancy, and the strict general rule is that every tree and plant planted by the tenant without any agreement to the contrary and not as a trade fixture, will become the property of the landlord and cannot be removed by the tenant at the expiration of his tenancy. Of course, if he happens to be a nurseryman, he can remove trees and the like planted for the purpose of his trade, just as he could remove a greenhouse erected for a similar purpose.

Lastly, with regard to the actual removal of the fixtures which are claimable by the tenant, apart from any special statutory provisions or special agreements, they must be removed before the expiration of the tenancy. This point should be remembered, since after the termination of the tenancy the tenant has no legal right to go on to the land and take away anything he has left there, unless, of course, he first obtains the consent of the owner of the land to his doing so. Harold Sharman.

GLASSHOUSE SANITATION.

GLASSHOUSES, like human habitations, require to be thoroughly cleansed periodically if the health of the occupants is to be maintained at a high standard. This is becoming more than ever a necessity as a result of the rapid spread of red spider (*Tetranychus telarius*) during the past few years in commercial houses.

It has been clearly demonstrated that this pest may be effectively controlled on Carnations (*T. Parker, Gard. Chron.*, Oct. 23, 1926) by vaporising naphthaline at prescribed concentrations and under certain conditions of temperature, etc. Similar treatment may be applied to certain other glasshouse plants, but with greater risk of damage than in the case of Carnations, which means that this method must be carried out by a careful and observant operator. In spite of this, however, fumigation would still appear to be the most rational method of control, owing to ease of application and economy in time and labour.

Without in any way deprecating the practice of spraying, it must be recognised that it is not the most economical method, because a spray will only kill where it touches, hence the success of such a practice depends upon the thoroughness with which it is applied and the ability to reach the undersides of the foliage. The latter presents great difficulty, especially when treating a house thickly populated with Tomatos. Considerable progress has been made with sprays for controlling red spider, especially with petroleum emulsions. The petroleum must, however, be of a certain gravity and viscosity, and free from certain deleterious compounds containing sulphur. But such emulsions and sprays can only be looked upon as emergency measures, and for obvious reasons should be applied at the first signs of appearance of the pest, before it has had a chance of disseminating itself and becoming firmly established.

Various methods and materials have been suggested for the autumn and spring cleansing of glasshouses, i.e., when empty; but in the writer's opinion they are all defective in one respect, namely, that their application is too long delayed to be of much benefit.

Let us consider the matter from a slightly different angle. Red spider, like certain other insects, hibernate during the winter months, and it would appear feasible to assume that those of an early hatched generation would seek a place of hibernation sooner than those hatched later on in the season.

There would appear to be a massing of the forces prior to seeking shelter, judging from the severity of attacks which generally occurs during August, when the plant's vitality is naturally on the wane. Hence, it logically

follows that the best time to attack is prior to the general migration of red spider from the plants, and so prevent them from reaching the cracks and crevices under the ridge boards and other places of shelter, for it is well known that they favour such positions in which to hibernate.

It seems pretty certain that migration takes place so soon as the plants begin to weaken and die off, a condition which is influenced by the prevailing climatic conditions.

In the early autumn of 1926 the writer, in conjunction with Mr. H. I. Kingston, started some tests to ascertain whether the red spider infestation in the subsequent season could be delayed or eliminated altogether by heavily fumigating (with naphthaline vaporised in lamps) the preceding crop prior to pulling it out and while the plants were still green and the spider in an active condition. High concentrations were used and the houses treated during the day time so as to utilise sun-heat and maintain a fairly good internal temperature. These were followed by a fumigation with formaldehyde vaporised in the same way, the object in this instance being to destroy, if possible, spores of *Cladosporium fulvum*.

An examination of the state of the red spider was carried out prior to and after fumigating with naphthaline, by counting under the microscope, to ascertain the effect of the fumigant. These are shown below:—

NAPHTHALINE FUMIGATIONS.

| House. | Red Spider. | | Red Spider. | |
|--------|--------------------|----------|-------------------|-----------|
| | Before Fumigating. | | After Fumigating. | |
| | Active. | Inactive | Active. | Inactive. |
| A. | 60.7% | 39.3% | 0% | 100% |
| B. | 58.7% | 41.3% | 0% | 100% |

In both cases the adult white flies present were killed by the fumigation.

DETAILS OF FUMIGATION.

| Naphthaline Concentration per 1,000 cu. ft. | Duration of fumigation. | Temperature. | Size of House. |
|---|-------------------------|--------------|----------------|
| A. 14.3 ozs. | 24 hours. | 60-70° F. | 36,000 cu. ft. |
| B. 13.5 " | " | 60-70° F. | 44,000 " |

FORMALDEHYDE FUMIGATIONS.

| Concentration per 1,000 cubic feet. | Duration of fumigation. | Temperature. |
|-------------------------------------|-------------------------|--------------|
| A. 5 fl. ozs. | 24 hours. | 60-70° F. |
| B. 5 " | " | " |

The plants appeared to suffer little effects from the fumes of formaldehyde, even young shoots exhibiting no sign of scorching. It was therefore considered that it might be worth while making further trials to find out whether this method could be utilised at low concentrations during the growing stages of the plants, as a means of controlling mildew.

Observations were made periodically during the growing stages of the crops planted in these houses this season. Whilst no counts were made, it was observed that red spider appeared later in the treated houses as compared with others on the same nursery which had received the usual washing down, etc.

Throughout the season the plants were rather weak, but up to the end of October were free from mildew.

Although no definite claims can be made on a one-season's trial, the results are of sufficient interest to make it worth while to repeat the trial on a much larger scale, and, in any case, this new method would be much cheaper than washing down with emulsified cresylic acid, which involves much time and labour.

A series of fumigations carried out with formaldehyde, using a concentration of ten and twenty fluid ounces per 1,000 cubic feet, produced little effect upon adult white fly or red spider, but naphthaline gave one hundred per cent. kill of adult fly and appeared to have had some effect upon the nymph stage; caterpillars also

seem unable to withstand the fumes of this material.

In applying this method of fumigating to commercial conditions, and in order to obtain the best results, it would appear desirable to fumigate in September or early October; this would mean "bench ripening" the remainder of the crop, and would probably be compensated for by a longer period of freedom from troubles during the subsequent season.

As most of the "washing down" with such materials as emulsified cresylic acid is carried out during November and December, when, in all probability, the red spiders have reached their winter quarters, it is not to be wondered at that very little good accrues from such treatment, for in spite of this annual "washing day," red spider appears in as great numbers as before.

It is very questionable whether burning sulphur is of much avail, although there are still many growers who adhere to this old practice. Because the fumes of burning sulphur irritate the nose, eyes and throat of human beings it does not necessarily follow that they produce any effect upon red spider.

"Tear gas" has been used for end-of-season fumigations, but the concentration that must be maintained to destroy red spider, or its eggs, makes the operation a most unpleasant one, with a certain amount of danger to the person applying it. The system of sprinkling this material on to the soil is to be deprecated, as the soil is likely to retain it for a considerable period with consequent disastrous results to the seedlings at planting-out time. *Theodore Parker.*

DISEASES AND PESTS OF CELERY IN 1927.

DURING the year now closing, Celery has suffered considerably from various causes in different parts of the country. The cold, wet season, no doubt, helped to produce indifferent results, but cultural details have also played their part in assisting the various organisms to obtain a firm hold upon their host, with the result that the value of the crop has been reduced. No attempt is made in this article to denote which disease or pest has done the most damage, because the damage and organism have varied in different parts of the country, but an attempt is made to record the diseases and pests seen, and to correlate the effect of weather and cultural operations upon the organisms concerned.

The writer has had the privilege of examining damaged specimens of Celery plants from many parts of the country and from these specimens it appears that the damage falls into four groups, namely:—(1) Leaf Blight; (2) Carrot Fly; (3) Soft Rot; (4) Pithy sticks. Average crops have been obtained in gardens where the above troubles were absent, showing that the weather is not wholly to blame, but in gardens where one of the organisms has been present it seems as though bad weather, plus the organism, has operated against the plants, and poor crops resulted.

LEAF BLIGHT (SEPTORIA APII, BRI. AND CAD.)

This disease has taken a large toll in many widely separated parts of the country; it appeared early in the season and when no effort was made to control it, was troublesome throughout the season. Recently, *The Gardeners' Chronicle* has called attention to this trouble when research work on the subject of Celery leaf blight was reviewed. The disease may appear at any stage in the life of a Celery plant, and it seems reasonable to suppose that when the disease appears in the seedling stage contaminated seed was the probable cause. On the other hand, when the disease did not appear until the plants were placed in their final quarters, contamination may have been caused by diseased crop remains, present in the soil or manure.

When there is much disease present in the seedling stage it points to a heavy attack on the parent seed plants during the previous season, and not necessarily to the effect of the weather factor after germination. There appears to be some evidence that a slow growing season assists

the disease to make rapid headway, but the writer would rather trust to preventive spraying than blame the weather conditions for a crop failure. It appears from the article noted above that this disease is present in most packets of seeds, and if so, some early method of control is essential.

CARROT FLY (PSILA ROSAE, F.).

It is only within recent years that this pest has been noticed as using Celery as a host plant, but the writer is of the opinion that this was due to the fact that previously the damage to Celery was either overlooked or more probably put down to other causes. In any case, the damage to Celery by Carrot fly during 1927 has been unusually severe. The pest was very common on its normal host so that a bad attack on Celery was, perhaps, only to be expected. As to why Carrot fly should have been so prevalent during 1927 is a difficult question to answer, but it seems doubtful if weather conditions had much to do with it. The writer has noticed that when Carrot fly is common, Carrot aphid is common too, and he has thought that there might be a connection between the two. Research workers have recorded that the Carrot fly is very fond of sweet substances, and it appears likely that the Carrot fly feeds upon the honey dew excreted by the Carrot aphid. The effect of Carrot fly on Celery is that the maggots' tunnel in the outer leaf stalks and produce rusty marks in the positions attacked. If the attack has been bad, the Celery, when earthed up, rots, because soil organisms enter the wounded tissues and ordinary putrefaction is set up. A bad attack of Carrot fly is nearly always followed by a rotting of the plants from the outside towards the centre.

SOFT ROT (BACILLUS CAROTOVORUS, JONES).

Many cases of this rot have been received, and it would appear that season and culture have helped the organism. It may be only coincidence, but in all cases examined the plants attacked have been running to seed. In some instances the "bolting" was very pronounced, in others only just noticeable. We know very little about the cause of "bolting," but it is generally accepted that a bad season, or a check due to bad culture, assists in making Celery bolt. From the specimens examined during 1927, the writer is of the opinion that soft rot is likely to attack a plant running to "seed" after earthing. Soft rot is a difficult trouble to control because it attacks many of our crops in widely separated Orders. Diseased plants should be burned and a good rotation adopted. Watering a Celery trench with a solution of permanganate of potash helps to give the plants a good send off in their fight against soft rot. The treatment should be given before the plants are put into the trenches. It should be noticed that when soft rot occurs the rot commences in the centres of the plants and works outwards.

PITHY STICKS.

The cause of this trouble is unknown. Several cases have been examined wherein every part of the plant has been woolly and useless. It appears likely that culture and not season is the cause of this trouble. In one case the owner admits selecting three dozen plants, placing them in specially prepared trenches, and feeding liberally to produce sticks for exhibition purposes. The rest of the plants were grown as an ordinary crop. Every one of the three dozen plants selected for exhibition were pithy when lifted; not one pithy specimen was found in the crop grown under ordinary garden conditions.

In another case the owner stated that he had been growing the Celery for exhibition and had grown it well, the sticks looked perfect until lifted, and then they were found to be pithy. This evidence is certainly very slender; but it does seem that over feeding, or perhaps unbalanced feeding, can cause this trouble.

Pithy sticks are often to be found amongst commercially grown Celery, especially if quick-acting, nitrogenous manures have been used in excess.

It is interesting to note that one pest of Celery which is often troublesome has behaved remarkably well this season, namely Celery fly (*Acidia heraclei*, L.). The writer has seen very little of this pest, and no reports of damage have been received. *Somerset.*

FRUITS IN 1927.

EACH season brings with it its peculiar problems and, if we are wise, teaches its lessons. The fruits of the past year have been far from successful. That which survived the disastrous spring frosts came tardily to ripeness, and when they reached the dessert table were found sadly lacking in flavour. As was natural, the mid-season Apples and Pears suffered less, but when we came to our Cox's Orange Pippin, Blenheim Pippin, Ribston Pippin, and all the delightful family of Reinettes and Russets, we found them deprived of their usual flavour, the autumnal ripening having been lacking for want of sunshine.

It would seem at first glance that this is a stroke of fate which we cannot avoid, short of the futurist visions of supplemental electric rays. But perhaps we may mitigate in some degree the worst effects of a sunless year by treating the ripening of our fruits by another method, namely, the stopping of late autumnal growth always induced by a wet season. The ideal fruit-ripening climate is one of considerable autumn drought, absence of rain in August and September having an extraordinary effect upon the quality of fruit; who will forget the Cox's Orange Pippins of the vintage year of 1921, a year equally good for Pears and Grapes.

In my nursery this year the best finished Apples were from cordons on the Doucin Ameliorée stock, which has the character of stopping growth earlier than some of the other Paradise stocks and thus causing a premature autumn to the fruit. These cordons were also on a very dry and light soil where fruits always ripen early on whatever stock it may be.

The higher colour of Apples from such sandy, well-drained soils is well-known, and from this it would seem that a dry soil has an influence which might help to mitigate the loss of sunshine.

Some of the old gardeners recommended the use of boards to throw off the rains from the roots of Apricot trees and so provide a dry autumnal root-run such as the Apricot loves.

I have never seen this idea adopted or recommended for other fruit trees, but it would seem worth a trial, and a few sheets of corrugated iron suggest themselves as convenient material.

Most discoveries in horticulture are really re-discoveries, and perhaps one of our successful exhibitors has long been using this method. An extension of the experiment, if such it be, might be made to provide a dry soil in May, a month of vital importance to the fruit crops of the following year.

Most fruit growers will have noticed that there is a good set of fruit buds on Apples this year, and it was evident in June that this would be so, notwithstanding a good crop of fruits already set.

This, I imagine, was due to the dry weather of May, which tended to keep the young spurs from growing, and led to the formation of the desirable, terminal fruit bud rather than of the leafy lateral.

The creation of an artificial spring drought might, perhaps, have the same effect, and it would be worth trying on trees with a limited root-system, such as cordons and small bushes, or upon wall trees where the roots are in a limited space. *E. A. Bunyard.*

FRUIT GARDEN.

APPLE LAXTON'S SUPERB.

IN view of the prominence given recently to Apple Laxton's Superb, and the opinion held by many of the best fruit-growers that it may eventually prove to be the Apple everyone has been looking for to follow Cox's Orange Pippin, the following particulars of a tree which I saw growing in a garden in Berkshire in September last may be of interest.

The tree in question was carrying a splendid crop of good-sized and fairly well-coloured

fruits, and looked extremely healthy. The owner, a farmer, is particularly keen on fruit-growing, keeps fairly up-to-date with new varieties, and does not hesitate to discard a variety which is not to his liking, or to head back the offending tree and regraft it with another sort.

This latter fate befell a tree purchased in 1911 as Alfriston, but about which he said "If Alfriston is a respectable Apple, this certainly was not, as it was a small, hard, green Apple of no use at all."

"Small" does not suggest Alfriston, but the colour does; whether the tree was true to name is therefore not certain.

Laxton's Superb was the variety chosen to work on the headed-back branches. The grafts were put on in the spring of 1923 and have in the meantime grown and made a good tree.

The total weight of the crop gathered this year was 65 lbs., which may be considered an excellent result, and proves the cropping capabilities of the variety. It also indicates, assuming the original tree to be Alfriston, that Laxton's Superb "takes well" on it. *A. J. Cobb, Reading.*

THE MIRABELLE.

THE Mirabelle is well-known to all travellers in France as the fruit from which a delicious preserve is made, and to some as a liqueur of somewhat pungent quality.

It is specially grown in the regions of Metz and Nancy, and the names of these towns are often attached to it.

Of its early history little seems to be known, it has, like so many of the good things of France, been "taken for granted" that it is a native fruit. The first record I have found is in Duhamel du Monceau's *Arbres Fruitières*, published in 1768.

German authors seem to have received it rather later, but the writers of the nineteenth century, such as Overdieck, Dittrich Hinkert, etc., all call it "Gelbe Mirabelle," so it probably came to them from France.

It is a small, golden-yellow fruit, thickly dotted with crimson-red spots, and the ripe fruits look as good as they taste. It needs, however, a touch of fire to develop its finest qualities, and it is in the jam pot that it attains its apotheosis.

Like most popular fruits, it has, in the course of its life, developed several "forms," or sub-varieties, and the large-fruited one known as the Grosse Mirabelle can be recommended as having attained size without the loss of quality.

It will grow to a moderate-sized tree, being bushy in habit.

Any gardener who wishes to obtain the goodwill of the housewife should certainly try this most ready means of doing so. *E. A. Bunyard.*

FRUIT REGISTER.

PEAR ROUSE LENCH.

THIS old Pear is found in gardens in the west and midlands, and whilst not in any way comparable to Josephine de Malines and other late varieties, well-matured fruits are quite good.

The fruit is large, pyriform, uneven and undulating; skin pale green, turning to pale yellow, with bright russet markings, when ripe. The eye is large and open, reminiscent of Jargonelle; the flesh is yellow, juicy and of good flavour in January and February.

This variety was raised by Mr. T. A. Knight, the name being derived from the village or estate of Rouse Lench, near Evesham. The tree is excellent in bush or pyramid form. *Ralph E. Arnold.*

[Dr. Hogg (*The Fruit Manual*) describes the flesh of Pear Rouse Lench as "yellow, buttery, juicy, sugary, and pretty good flavour."—Eds.]

VEGETABLE GARDEN.

RHUBARB.

RHUBARB is an accommodating subject and, consequently, is often neglected. The best crops are produced on deep, alluvial soil, but good results follow on almost any kind of soil that has been heavily manured. The situation chosen for growing Rhubarb should be sheltered from east winds, but remote from trees. If the ground has been trenched and manured during the winter a dressing of bone-meal forked into the surface before planting in the spring will have a very beneficial effect upon growth.

Strong-growing varieties require a distance of three feet apart each way. The less robust kinds, as well as roots intended for forcing, may be planted from two to two-and-a-half feet apart, according to the variety. Stalks should not be pulled during the first season.

Old plantations should be kept clean and have some well-rotted manure forked into the soil during the autumn. Such plantations will continue to yield well for several seasons, but it is advisable to make a new one every third or fourth year.

Rhubarb may be raised from seeds, and a large stock is quickly secured by this means. Seeds sown in boxes filled with good soil during March or April germinate freely if the boxes are placed in a cool house or frame. The seedlings may be pricked out into boxes, or on a bed under a frame, and planted out during May or June.

Rhubarb is easily forced in any structure where a temperature of from 55° to 65° is maintained. Darkness is essential in producing stalks of good quality. Forcing may commence in November, and be continued until the outdoor crop is ready for use. Early varieties in the open ground may be forced by covering the roots with pots or boxes and surrounding these with litter and leaves.

There are many varieties of Rhubarb. Glaskin's Perpetual is a precocious sort, which produces stalks of good quality during the first season from seed, if grown in rich soil and given protection during severe weather; it will also continue in bearing for a long period. Stalks of the Sutton Rhubarb are large and tender, and of a rich, bright red colour. Hawke's Champagne is a superior, early variety, producing very long, straight, good-sized stalks of a bright red colour and of distinct flavour when cooked. Elford is excellent for forcing; the stalks are rather slender and retain their bright red colour when cooked. Myatt's Victoria is excellent for late use, producing long, thick, rich crimson stalks of good quality. *C. Ruse.*

HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

Birds and Fruit.—One important aspect of the subject of the havoc wrought amongst choice fruit this season by blue-tits seems not to have been touched upon by any of your numerous correspondents. I refer to the fact that these exceptionally severe attacks are of distinctly periodic occurrence. I have observed this to be the case over a period of twenty years, during which I have been an exhibitor of hardy fruits at the R.H.S. shows. I experienced similar trouble with tits, once in every few years, at Bessborough, in southern Ireland, and the same periodic rule seems to apply here in Sussex. This is my fourth summer here, and it is the first season during which I have had serious trouble from tits; indeed, I have experienced the worst visitation ever known to me, notwithstanding the usual safeguards. The trees were netted early in August. We then enclosed upwards of two hundred of the best fruits in hexagon bags, but not more than one in ten of these escaped the tits. The usual excuse one gets from the uninformed bird-lover is that birds

only attack fruits when they are thirsty, and the remedy is a supply of bird baths, pans of water, etc. My answer is, that during the unusually wet and cool month of August last, we lost thousands of beautiful Pears and Apples, through damage done to them by tits. It may well be that during this miserably cold, wet summer, some of the more usual food of these birds was lacking, but there was no lack of moisture. I was sorry to read in Mr. Durham's observation that paper bags proved useless also, as I had intended using these next season, instead of the hexagon material, which was so easily pecked through. One rather amusing aspect of the matter was that these birds develop enough intelligence to know that hexagon bags usually contained something extra good; so much so, indeed, that fruits of hard, green Apples, such as Lord Derby, enclosed in bags, were pecked, whilst exposed fruits on the same trees were left untouched. *T. E. Tomalin, Stanstead Park Gardens, Emsworth.*

— On the subject of the blue-tit and damage to fruits, Mr. H. E. Durham has the temerity to endeavour to overthrow the researches of Mr. Collinge. I put it that way because there happens to be this vast difference between these two gentlemen: Mr. Durham is obviously deeply prejudiced, and regards the blue-tit solely from the point of view of his lonely dessert table; Mr. Collinge is entirely unmoved by any sort of prejudice, the one wholly impartial authority for whom we have all been looking these many years who can convince us with facts that none can doubt as to the amount of good done by this bird or that. Now, is the man of average intelligence who desires a sound verdict on such matters to heed Mr. Durham or Mr. Collinge? We are all liable to squeal about our little personal hurts. Mr. Durham had only one Doyenné du Comice Pear on his table. That is obviously a tragedy of the first magnitude to Mr. Durham because it reminded him of the absence of the remaining seventeen Pears! But are all the tits of his locality to be condemned on that account? I am afraid it takes more than Pears, even Doyenné du Comice Pears, to make a world, and Mr. Durham must learn to "live and let live." His simile of the fox fails as an argument because it is false in its application, and I will invite him to take from me an illustration a little nearer the mark. A single stoat in my garden will keep it entirely free from voles and mice, which swarm when the stoat is absent. That stoat is killed by my neighbour's keeper because it takes a pheasant's egg. The keeper would extirpate every stoat just as Mr. Durham would extirpate every blue-tit, each acting purely and selfishly in his own narrow interests. Everyone else who may happen to derive great help from those creatures may go to the place where the worm never dies. That sort of thing will not do. The community has the prior claim, the larger voice. I am both a gardener and a lover of most birds. Once, as a market gardener and fruit grower, I suffered from the latter as much as anyone. But I hope I have always been sane enough to regard this matter with both eyes open and some measure of fair judgment. Mr. Durham, in his efforts to blacken the blue-tit's character, has simply disclosed his own. "My garden" and "my crop" are all he sees, thinks or cares about. But it so happens that there are a few other people in the world besides himself, people unbiassed enough to view the matter in the light of common justice and common sense. *A. T. Johnson.*

Celastrus articulatus.—I have read with much interest the appreciative notes on *Celastrus articulatus* on page 484, and would like to express concurrence with all that your correspondent writes in its favour. It is exceedingly attractive when in fruit, and cut branches bearing these fruits look remarkably ornamental. The only point to be made against its more general introduction to gardens is that of its vigorous habit, which is mentioned by your correspondent. It must be planted with judgment, as its twisting branches would strangle some subjects which were too near. The positions suggested in your contributor's notes seem ideal for the purpose. *S. A.*

SOCIETIES.

GUILDFORD AND DISTRICT GARDENERS'.

LORD MACAULAY, in his essay on Milton, has a sentence which very well fits the lecture delivered by Mr. A. E. Burgess, at Guildford, on December 6.—

"Every generation enjoys the use of a vast hoard bequeathed to it by antiquity, and transmits that hoard, augmented by fresh acquisitions, to future ages."

Whatever of truth there may have been in this statement relative to the matter upon which Macaulay was writing at the time, one could but feel it was certainly true of "The Apple." Mr. Burgess began his lecture on "The Making of an Apple Tree," with a backward glance, and said it had taken hundreds of years, and hundreds of people to make the Apple—and to bring it to its present stage, which, however, is still far from perfect. There is work and scope for other men in future years to produce the perfect Apple. Instances were given to prove that the Apple was in cultivation four thousand years ago. The English Pearmain is the oldest variety known to us, but The Lady Apple of to-day is exactly the same Apple as was known to the Romans. Mr. Burgess thought that the original Apple was the Crab, still found along the hedge-rows, and that the early improved varieties were chance seedlings. He then went on to speak of the work and experiments of Mr. Knight, Mr. Thomas Laxton and Mr. Charles Ross, and from this point passed under review various methods of propagation, by budding and grafting with special mention of the experiments carried out at East Malling. The proper methods of budding and grafting were demonstrated, and the correct method of pruning was illustrated by some excellent diagrams prepared by Mr. Middleton, also of the Surrey Council, who accompanied the lecturer. The French system of pruning adopted by M. Lorette was also brought under review.

The President, Alderman W. T. Patrick, J.P., expressed warm thanks to Mr. Burgess for his very informing and interesting lecture, and to Mr. Middleton for his part in it.

An extremely good collection of Apples, and other produce had been brought by members to whom Certificates were awarded.

TAUNTON AND DISTRICT CHRYSANTHEMUM AND FRUIT.

THE new departure of the above Society in holding a two-days show this year was fully justified by an increased number of exhibits and a large attendance. The County Territorial Hall at Taunton was found to be too small and some of the sections were placed in a tent adjoining the hall.

The Society is fortunate in its officials, for the President, Lt.-Col. A. Hamilton Gault, D.S.O., and his lady, take a practical interest in the Society and its doings, while the secretarial work is most ably carried out by Mr. W. H. Loosemore.

The President's Cup, which is offered for the best group of Japanese Chrysanthemums, was awarded to Mr. GUY TURNER for a tastefully arranged collection of well-grown plants. Mr. TURNER also won four first prizes for specimen Chrysanthemum plants of the different types, and also won first prizes with four plants of *Salvia splendens* and with six *Begonias*. There were two large groups of Single Chrysanthemums, and the first prize was won by Mr. G. U. FARRANT with an admirable display, while Mr. GUY TURNER was a good second. The best display of cut blooms was arranged by Mr. DOUGLAS REED.

In the open classes for exhibition blooms, Messrs. JAMES WEBBER AND SONS were the most successful exhibitors, for they won seven first prizes, including two Silver Cups, three second prizes and, with a magnificent bloom of *R. C. Pulling*, the Gold Medal offered for the best bloom in the show. In each of the two principal

classes the LADY ABBESS, Francisca Convent, Taunton, was a very close second. Alderman F. W. PENNY was a very successful exhibitor in the amateurs' classes and won the Challenge Cup offered for the highest aggregate of points.

The Decorative Classes were very successful. There were seven exhibits of dinner-table decorations and many bowls, vases, baskets and bouquets of Chrysanthemums. Miss E. DOBBS and Miss E. B. ELLIS were the most successful exhibitors.

Decorative displays of fruits and flowers were an attractive feature of the show. The Gold Medal for the best display on a fifteen feet run of tabling was won by Mr. A. J. GROVES, Chantry Gardens, Taunton. In the classes for single dishes of fruits there were over two hundred dishes of Apples, while the entries for other fruits and vegetables were also very numerous, and the quality reached a high standard of excellence.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

At the meeting, held on Friday, December 16, the members of Committee present were:—Mr. J. B. Adamson (in the chair), Mr. A. Burns, Mr. B. Collins, Mr. A. Coningsby, Mr. J. Evans, Mr. A. Keeling, Mr. G. V. Llewelyn, Mr. D. McLeod and Mr. H. Arthur (Secretary).

FIRST CLASS CERTIFICATE.

Laelia Schrodærae var. *Sunray*.—A large, well-formed flower with pure white sepals and petals and a large lip that has a deep band of velvety crimson. From J. B. ADAMSON, Esq.

AWARDS OF MERIT.

Cypripedium Pyramus var. *The Premier*; *C. Montcalm*, Townley Grove var.; *C. Pliny* var. *magnificum*; *C. Memoria F. M. Ogilvie* var. *Imperator*; *C. Alcivarna* var. *Radiant*; *C. Bisham* var. *giganteum*; *C. Everest* (*Hestia* × *Swintonense*); *C. Olympus* var. *Invincible*; *C. Luna* (*Desdemona* × *Mrs. Carey Batten*) and *Laelio-Cattleya Asprey* (*Aphrodite* × *C. Dowiana*). All from J. B. ADAMSON, Esq.

Cymbidium Doris var. *Ajax*; *C. Moira* var. *Livid*; and *Odontoglossum L. R. Harrow*.—From The Hon. G. E. VESTLEY.

Potinara Amalthea (*Brasso-Cattleya Digbyano-Mendelii* × *Sophro-Laelio-Cattleya Marathon*) and *Lycaste Skinneri* var. *Hecate*.—From Mrs. BRUCE and Miss WRIGLEY.

Cypripedium Mrs. Ethel Rhodes (parentage unknown).—From G. V. LLEWELYN, Esq.

AWARDS OF APPRECIATION.

To *Cypripedium Rhoda A. Llewelyn* (parentage unknown), and *C. Southport Gem* (*Mulatto* × *Druryi*).—From G. V. LLEWELYN, Esq.

CULTURAL CERTIFICATE.

To Mr. J. HOWES for *Laelio-Cattleya Schrödærae*.

GROUPS.

J. B. ADAMSON, Esq., Blackpool (gr. Mr. J. Howes), staged a group to which a Gold Medal was awarded. This included *Cypripediums* already enumerated in the awards, and, in addition, *C. Christopher bisepalum*, *C. Stamperland*, *C. Warrior*, *Green's* var., *C. Alabaster*, *C. Corsair*, *Holford's* var., *C. Charlotte Dillon*, *C. The Prince*, *C. Elatior*, *C. Leeannum* var. *J. Gurney Fowler*, and *Odontoglossum J. H. Knight*, *O. amabile splendens* and *O. Humeannum*.

Mrs. BRUCE and Miss WRIGLEY, Bury (gr. Mr. A. Burns), were also awarded a Gold Medal for a group containing *Cypripedium Invincible*, *C. Boag*, *C. Troilus* var. *Impregnable*, *C. Eboriacum*, *C. The God Pan*, *C. Queen Mab* var. *Fairy*; *Lycaste Skinneri* var. *Hecate*, *L. S. delicatissima*, *Sophro-Laelio-Cattleya Osmondii* and *Masdevallia towarensis*.

Mr. JOHN EVANS, Colwyn Bay, was awarded a Large Silver-gilt Medal for a group in which

were well-flowered plants of *Vanda caerulea*, *Odontoglossum crispum* in variety; *Odontioda Diana*; *Oncidium tigrinum* and *Cypripediums* in variety.

Captain W. HORRIDGE, Bury (gr. Mr. A. Coningsby), exhibited *Cypripedium Aeson*, *Bolholt* var., *C. Louvain*, *C. Swallow*, *C. Rosettii* and *Miltozia Wm. Pitt*.

MESSRS. KEELING AND SONS showed *Cypripedium Chrysostum*, *C. Golden Fleece*, *C. Pyramus*, *C. Carola* and *C. Nesta*. Mr. D. McLEOD also showed *Cypripediums*.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

THE monthly meeting of this Society was held in the R.H.S. Hall, on Monday, December 12, when Mr. T. R. Butler presided. Eight new members were elected. Four members withdrew interest from their deposit accounts, the total amounting to £14 12s. 2d., while three members over the age of seventy years withdrew from their deposit accounts sums amounting to £18 15s. 5d. The nominee of one deceased member received £29 15s. 10d. The sick-pay for the month on the Ordinary side came to £87 2s. 2d., and on the State section to £72 16s. 8d.; maternity claims totalled £7 10s. 0d. Grants from the State section, amounting to £34 8s. 0d., were made to nine members for dental and surgical treatment; nine other cases were considered.

TRADE NOTE.

THE many friends of Mr. Alfred Gray, who is connected with the firm of James Gray, Horticultural Builders, Chelsea, will be pleased to learn that he has now entirely recovered from his recent indisposition.

Obituary.

John Birch.—The death of Mr. J. Birch occurred at Styche Hall Gardens, on the 11th inst., after a short illness. Mr. Birch was sixty-three years of age and a well-known Shropshire gardener. He spent his early years at Tedsmore, West Felton, and when quite a young man went to Shotton Hall, the seat of the late Marquis of Cambridge, where he took an important part in laying out the gardens. Later, he became gardener and bailiff to the late Lady Mary Herbert of Styche, at Styche Hall, and held that position for the past twenty years. Mr. Birch was a keen and enthusiastic gardener, devoted to duty and a thorough believer in "what is worth doing at all is worth doing well." He was a man of singularly happy disposition, deeply respected by his employer and all those who came in contact with him. He led a most active life, and was an annual and successful exhibitor at the great Shrewsbury Show, and one of the oldest members of Committee of that exhibition, having been elected in 1899. His cheery personality was well known to exhibitors and judges, as he himself judged in the cottagers' section for nearly thirty years. Mr. Birch was a member of the Moreton Say Parish Council, and Treasurer of the Moreton Say Fund for Hospitals. The remains were laid to rest in Moreton Say churchyard on the 15th inst., amid tokens of the greatest respect. His widow, two sons and a daughter sadly mourn their deep loss.

Comte Ferdinand de Hemptinne.—We learn that Comte Ferdinand de Hemptinne, of Ghent, died suddenly a few days ago. He was seventy-two years of age and, like most members of the family, took a keen interest in the great horticultural industry of his country.

F. J. Harrison.—It is with very deep regret that we record the death of Mr. F. J. Harrison, one of the most enthusiastic of the northern amateur cultivators of Roses and a most successful exhibitor of these flowers. Together with the

late Mr. George H. Mackereth, he was one of the founders of the North Lonsdale Rose Society, and acted as its Treasurer from the time of its formation in 1884. He also assisted in the organisation of the Saltaire Rose Society. As Chairman of the North Lonsdale Rose Society, and of the Ulverston Allotment Holders Association, he was very widely known in the Ulverston district, and also in the north of Yorkshire, while many southern growers of Roses and Sweet Peas made his acquaintance during the years prior to the war.

ANSWERS TO CORRESPONDENTS.

APPLES DISEASED.—*P. G.* The Apple sent is affected by scab disease. Syringe the tree with sulphate of iron and next spring spray with diluted Bordeaux mixture, just when the buds are beginning to open, again when the petals are falling, and a third time when the young fruits are about the size of Peas.

AMARYLLIS BELLADONNA.—*J. S. C.* Provided the situation has been chosen carefully, there should be nothing unusual in the flowering of *Amaryllis Belladonna* in east Yorkshire.

CYCLAMENS.—*R. W. R.* The leaves submitted were infested, more or less, with mite and thrips. Dip the plants in a nicotine insecticide and afterwards dust the undersides of the leaves with tobacco powder.

CYCLAMEN ROOTS INFESTED WITH BEETLES.—*F. B.* The "beetles" are those usually known as vine weevils, and are frequently found in soil containing a large percentage of leaf-mould. If the infestation is a very bad one, it may be necessary to shake the roots free from the soil they at present occupy and repot them in sterilised material; submerging the pots in lime-water will compel the weevils to rise to the surface, when they may be caught. It is always desirable to sterilise leaf-mould before it is used for potting.

FUNGUS IN MANURE.—*A. B.* The fungus is *Coprinus stercovarius*, growing from a sclerotium. This fungus does not always grow from a sclerotium, but sclerotia are not uncommon in damp manure.

RE-TURFING A BOWLING GREEN.—*G. R.* If the bowling green is treated in sections, as suggested, there would be considerable difficulty in making uniform levels. We should prefer to strip all the turf and then dig the whole area. The possibility of injury from frosts to the stacked turves could be met by a covering of dry litter, Bracken or some similar material. If, as we suspect, it is found that the original turf which was turned in when the green was first made, has not fully decayed, it should be forked out during the digging.

ROSES UNDER GLASS.—*W. A. B.* It is rather late in the season to expect the best results from Roses potted up after this date. To obtain Roses in perfection a heated house is necessary, even if they are not wanted to bloom before April or May. Some of the most delicate and beautiful varieties which suffer from winds and rain in summer and from frost in winter, are specially suitable for growing under glass. Many climbing Roses lend themselves to this mode of culture. Early autumn is a good time to pot up Roses from the open ground; six-inch pots will be found suitable for most varieties, but very strong-growing and well-rooted plants may have larger pots. Use clean, carefully crocked pots, cut away damaged roots and do not place the plants too low in the soil. Weak and unnecessary growths may be thinned out at the time of potting, shortening the others when the plants have made fresh roots. Once established, however, the earlier they are pruned the earlier they will flower. At this late season they may be placed in a cool house and protected from frost, or, if required to bloom just before their natural period, they may be plunged

in ashes in an open spot in the garden. A Roses like a fairly rich soil. Good turfy loam, a little bone-meal, silver sand in proportion to the texture of the loam, and charred earth will improve the compost. The object throughout the growing season should be to get a few fairly stout, well-ripened shoots by the autumn. Watering with tepid water should be carefully carried out throughout the season of growth. When growing freely, feed the roots with diluted liquid manure and soot-water, and light dressings of an approved Rose manure. Keep a sharp look-out for the Rose grub, which is best destroyed by hand picking, and lightly fumigate the house to prevent attacks of green fly. Forced Roses are subject to mildew and red spider; dusting with flowers of sulphur is the best remedy for these pests. During the first year, the Roses should be brought on very steadily and not forced into flower before April or May; 40° to 43° at night and 50° to 55° by day, to commence with, will be quite high enough, gradually raising the temperature to 50° at night, and up to 70° by day, with sun-heat, as they advance in growth. Sudden and violent changes should be avoided and everything done to keep the plants clean and healthy. If fine flowers are desired, December or January is quite early enough to commence forcing, and unless the nights are very cold, air may be admitted for the first fortnight or three weeks to strengthen the buds, but so soon as the leaves are formed, the house should be kept closed until much later in the season, when the weather is mild. Gradually harden the plants off after they have flowered, placing them in a cold house to ripen up their growths. The same routine follows every year; in September or October all pot Roses should be repotted, stood in a half-shady position, and carefully watered. As a general rule, Roses require little water during the autumn and winter months, and after being forced they naturally go to rest earlier and are thus in the best condition for forcing again. They require rather closer pruning than outdoor plants.

STREPTOSOLEN JAMESONI.—*M. A.* The plant at present in a seven-inch pot should be shifted into a ten-inch pot early in the New Year; it requires a good root-run. It should not be necessary to prune your specimen next spring as this species does not flower freely unless exposed to full sunshine. *Streptosolen Jamesoni* is seen at its best when planted out in a well-drained border in a greenhouse, and the growths are trained up under the roof-glass and not shaded.

VINE BORDERS.—*W. C. M.* You give us no information concerning the crop your vines carried, or the width of the inside border, but neither the vines nor the border can be exhausted after seven years, if the border was made as you suggest. The roots should not have gone down into the drainage, therefore, the possible cause of failure is lack of water, the roots having gone down for more moisture. You may add an outside border and one three feet wide is quite sufficient at present. Lift the fibrous roots and remove the strong ones which have gone down into the drainage. Your best course would be to take out three or four feet of the addition you made to the inside border three years ago, carefully preserving the fibrous roots and laying them in nearer the surface, cutting all strong ones back to the face of the old border. Use the old soil, with the addition of fresh material, to lay the roots in nearer the surface. Add sprinklings of charcoal and bone-meal as the border is made, and a dusting of vine manure nearer the surface. Build up a turf wall, leaving a space at least one foot between the border and the path to be filled up with Oak or Beech leaves; tread the border and leaves as firmly as possible. Remove the exhausted leaves every year, cut back the roots to the turf and again fill the space with leaves; allow your vines more water during the growing season, and they will quickly recover if you feed them judiciously.

MARKETS.

COVENT GARDEN, Tuesday, December 20th, 1927

WE cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Tuesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in the day.—EDS.

Plants in Pots, etc.: Average Wholesale Prices.

REMARKS.—This should be one of the busiest weeks of the year in the cut flower trade. Prices will fluctuate according to supply and requirements. There is every prospect of a good supply of Chrysanthemums, both disbudded blooms and spray varieties, also of Lilium longiflorum. If the present severe weather continues it is difficult to suggest prices. There is likely to be a very limited supply of Carnations and Roses, and prices for these bloom may reach a high figure before Saturday next, as also they may for Richardias, if there is the usual demand for Christmas decorations. Daffodils, Hyacinths and Tulips have increased in quantity during the past week, but this is not likely to cause any reduction in price. White Lilac is now arriving in much better condition; a few sprays of mauve Lilac have been on sale this week. Iris tingitana and Poinsettias are very attractive for decorative purposes. The cold weather has shortened the supply of Violets from home-growers, and there is likely to be a very short supply during the next few days.

FRENCH FLOWERS.—These arrived to-day in a frozen condition and were practically useless. If the severe weather continues, these imported blooms will be greatly missed during the present week, as there is always a good demand just before Christmas for Narcissus, Anemones, Mimosa, Ranunculuses, Violets and Roses.

REMARKS.—The severe weather has been entirely unfavourable to the fruit trade. The demand has been checked and, in addition, considerable quantities of produce have arrived frozen and in some instances quite useless. Hothouse Grapes have been selling freely, as is usual at this time of year. Some Peaches and Apricots from the Cape have also sold fairly well. Oranges are plentiful; ordinary grades are comparatively cheap, but the higher-class Oranges have sold well at better prices. Imported Apples are not plentiful, but there are ample stocks for the present demand. First grade English Bramley's Seedling and the best Cox's Orange Pippins have been enquired for, but there is no improvement in the trade for medium-class fruit. The Christmas

shipment of Pineapples is a heavy one, about 12,000 cases, and the condition of the cargo is variable. The Nut section is fairly busy and the average price level is moderately high.

Tomatos from the Canaries are a heavy supply and quotations are easier. The small supply of English new crop Tomatos is popular, although prices are rather prohibitive. Cucumbers have reached an abnormally high price level, and this is probably due to the shortage caused by the weather. Guernsey Beans are making more money and reached the highest price this season. The shipments of Madeira Beans this week are in poor condition owing to frost. Mushrooms maintain a good price level but quantities are not heavy. Practically all French salads have arrived frozen and the Lettuces have been selling comparatively cheaply. Green vegetables are likely to reach fancy prices if the present severe weather holds.

GLASGOW.

Prices in the cut flower market displayed a little irregularity last week, but the general tone was firm, especially for Carnations, which advanced to 6s. and 7s. per dozen, and Roses, 8s. and 9s. for pink varieties, and 4s. to 5s. for red. Fewer Chrysanthemums were available at the following quotations: Phyllis Cooper and Mary Morris, 2s. 6d. to 3s. for 6's; Red Lincoln, Favourite, Duckham, Winter Cheer and Framfield Pink, 2s. to 2s. 6d.; Exmouth Crimson, 1s. 9d. to 2s. 3d.; Florrie King, 9d. to 1s. 3d.; Wilcox, 1s. to 1s. 3d.; Pink Triumph, 8d. to 1s.; Niveus, 1s. to 1s. 6d.; Heston White, 6d. to 9d.; and Balcombe Beauty, 2s. to 3s. per dozen. Lilium longiflorum averaged 4s. per bunch. Narcissi, 1s. 6d. to 3s. per dozen; and Asparagus Fern, 1s. to 2s. per bunch. Bowls of Tulips made 1s. 6d. to 1s. 9d. each.

The turnover in the fruit market was disappointing for the season of the year. Oranges were dearer, Jaffas 14s. to 16s. per case; Valencia, 13s. to 28s. according to counts; Mandarin, 1s. 2d. to 2s. per tray; and Grape Fruit, 20s. to 24s. Apples sold slowly, notwithstanding that this was Canadian Apple week, and prices were inclined to drop. Newtown Pippin sold at 16s. and 20s. per case; Jonathan, 10s. 6d. to 15s.; Grimes' Golden, 12s. to 15s.; Delicious, 14s. to 16s.; Winesap, 14s. to 15s.; barrel Apples were steady for Baldwin, Ben Davis, Spies and York Imperials, while Canadian Kings declined to 36s. for No. 1, and 32s. for No. 2. Grapes remained unchanged at 3s. to 3s. 6d. per lb.; Californian Winter Nels Pears, 25s. to 30s. per case; Tenerife Tomatos were practically unsaleable and were offered at 10s. per package.

In the vegetable market, Lettuce sold at 3s. to 4s. per dozen; Cauliflowers, 4s. to 5s.; Endive, 3s. to 4s.; and Mushrooms, 2s. to 2s. 6d. per lb.

Rothamsted Field Experiments II.

As is but natural in a commercial age, the value of dressings of fertilisers is measured in terms of increased yield of crop. Experiments at Rothamsted* reported by Sir John Russell indicate, however, that fertilisers may have a significant effect on the quality of the crop. This, indeed, is not surprising, for the compounds used as fertilisers may and often do contain other elements besides nitrogen, phosphorus and potassium. Chlorine, for example, is present in kainit (which is made up largely of potassium chloride) and in muriate of ammonia. Now it is known that the element chlorine, although not an indispensable plant food, does exert an influence on plant growth and behaviour. Buckwheat, for instance, when grown without chlorine compounds, reaches the flowering stage and then incontinently drops its flowers. Gardeners who use common salt for dressing Asparagus beds, though they usually regard the practice as a concession to the age-long habits of a maritime plant, may thus find a new sanction for this old practice. However that may be, there seems to be no doubt from the results of experiments at Rothamsted that the use of muriate of ammonia (ammonium chloride) on Barley induces that plant to produce more grains per acre than are found when nitrogen is given in another form, for

example, as sulphate of ammonia. The increase in number of grains is considerable, ranging in some years from a mere 330,000 to upwards of one-and-a-half million in other years. Even when the crop is no larger, the increase in number of grains still occurs. It looks as though the presence of chlorine made a difference to the fertility of the Barley florets. These facts are, of course, of special interest to gardeners. Self sterility which affects certain varieties of fruit trees is not always absolute. May it not be that applying a fertiliser containing chlorine—muriate of ammonia or muriate of potash—partial sterility might be overcome! Another direction in which a horticultural application of these facts might be found is in the manuring of early Potatos, and of maincrop Potatos in late districts. For, apparently, muriate of ammonia hastens maturity. Potato haulm yellows sooner when muriate of ammonia is used than it does when sulphate is substituted for it. This earlier maturity is, of course, advantageous in the case of early varieties, and in the case of late varieties of Potatos grown in late districts. It would, on the other hand be a disadvantage in the case of Potatos grown on early land. Herein may perhaps be found the explanation of the common opinion that potash salts or sulphate of potash are better forms of potash as a component of Potato fertilisers than is muriate. It would seem as though they are better in some climates, and in some soils, and not so good in others. These investigations open out a long vista of pleasing possibilities. Some day we shall, perhaps, know how to manure for quality as well as we know now how to manure for quantity. The subject appeals to the epicure. But it should appeal equally to all, even to those who set no store on the pleasures of the table. For it is a maxim of physiology that unless an animal enjoys its food it cannot fully profit by it. Flavour is an aid to digestion, and the best foods are those which evoke satisfaction in their consumption. There is, therefore, an ample field of experiment open to the private gardener. It is, however, not one into which he will venture precipitately, though he might try a few cautious experiments along the lines we have indicated. No doubt Rothamsted will persist in following this interesting line of research, and if so, we may presently expect fertiliser recipes for flavour of such sureness, that though we may never gather Grapes off Thistles, we may, especially in sunless years, find our Strawberries or Raspberries, and even our Apples and our Plums, more palatable than they are apt to be when sunshine fails to develop to the full their inherent capacity for delectableness.

"The Gardeners' Chronicle" Almanac for 1928.—Our Almanac for the ensuing year, giving the dates of the principal flower shows in Great Britain and of the meetings of horticultural and botanical societies, is now being prepared and will be published in an early issue of the New Year. Secretaries of horticultural, botanical and other societies are requested to send the dates of their shows, meetings, etc., so soon as possible, in order that they may be included in the Almanac.

Shortage of Rushes for Chairs.—There appears to be a shortage of fresh-water Rushes suitable for making chair-seats, baskets and mats, and for allied purposes, for the Director of the Rural Industries Bureau, 26, Eccleston Street, S.W.1, has appealed for information concerning any unused beds in various parts of the country, where there may be a marketable quantity. The best Rush for the above purposes is *Ruscus conglomeratus*. It is the Soft Rush, *Ruscus effusus*, which was used so extensively for supplying the wicks of the old tallow "dips."

Educational Garden, Singleton Park, Swansea.

—A list has been published of the seeds available for exchange and distribution from the Educational Garden, Singleton Park, Swansea. Over five hundred species are available. The list may be obtained—by those in charge of similar institutions—from Mr. D. Bliss, Parks Superintendent, 4, Prospect Place, Swansea.

Allotment Gardens of Scandinavian Cities.—

A stock of Potatos and roots for the winter, as well as enough vegetables to supply the summer needs, are often raised by garden farmers who till city-owned, vacant, suburban plots in Finland at very low rentals. Such allotment gardens are to be found in Helsingfors, Gumtack, Brunakarr and Sveaborg. The tiny villas built on the plots are used during the winter as sport sheds and as storehouses for the skis, sleds and skates of the families who come out on holidays for the snow sports. In the summer, the appearance of these garden groups is very attractive, so well is each square yard of ground cultivated. They offer recreation, states the *Monitor*, for the man who must work all the summer in the city, and for his family whom he may not be able to afford to send to the country. Here the wife and children may be out in the air all day, the older children helping to weed, and the little ones playing in a common Pine and Birch grove. A similar state of things exists in many of the large towns of Sweden and Denmark.

Golden Wedding of Kew Employee—On

Christmas Day, Mr. and Mrs. Abel Watford celebrated their golden wedding at the Royal Gardens, Kew. Mr. Watford, who is well-known to many generations of Kewites, is still engineer-in-charge of the pumping station, although it is expected that he will retire very shortly, and, as he resides in the official cottage, he has created a record in the annals of Kew. A few years ago, Mr. Watford's long service at Kew was rewarded with the M.V.O., which he received at Whitehall. He was the oldest member, and captain, of the Kew Palace Fire Brigade, which has been abandoned recently. In his younger days, Mr. Watford was an enthusiastic cricketer and, while a member of the Surrey County 2nd XI, he was chosen to play at Lords for the Southern Counties against the Northern Counties.

French Phytopathological Service.—The French

Ministry of Agriculture is organising a phytopathological service, similar to that already existing in a good many countries, for the protection of imported and exported agricultural and horticultural produce from pests and diseases.

Legacy to a Gardener.—Amongst recent

bequests appears a legacy of £50 by the late Mr. William Herbert Pets, of Dunkirky, Elgin, to his gardener, Mr. John Fraser.

Donation to the Royal Gardeners' Orphan Fund.

The Bournemouth and District Gardeners' Association annually organises a concert in aid of the Royal Gardeners' Orphan Fund, and this year, thanks to the enterprise and hard work of Mr. C. Nippard, of Ashton Lodge Gardens, Branksome Park, and his willing band of helpers, a donation of £24 has been sent to the Fund.

The Surrey Garden Village Trust.—Under

the above title the tenants of the agricultural small-holdings at Addington have formed a company and taken up 107 acres of additional vacant land. Previously there were seventy-seven holdings aggregating 202 acres, and these have been worked very successfully. Each applicant for one of the new holdings must have a working capital of at least £40 per acre and satisfy the Committee that he possesses expert knowledge of at least one branch of food production. The existing holdings vary considerably in extent up to a maximum of ten acres. General market crops are grown. There are small fruit plantations, and most of the small-holders keep pigs and fowls. The produce finds a ready sale in the neighbouring town of Croydon.

Christmas Weather.—With a brief rise in temperature, which only flattered to deceive, the wintry weather continued. On the Wednesday before Christmas, business people found the roads and streets almost impassable on account of the "silver thaw" which had set in. Fortunately, it is only very occasionally that we in this country, with all its changes, experience such climatic conditions. Cold rain fell during the night and early hours and froze as it fell. The supreme difficulties and casualties have been graphically recorded in the Daily Press, whose writers seem to have enjoyed the opportunity of delving into climatological records. By mid-day a warm current of air quickly dispelled the treacherous ice from the southern parts of the country and the rain continued, dispelling all expectations of a "White Christmas." But, as we anticipated when writing last week's note, the change to mild conditions was very temporary. On Christmas evening snow fell heavily, thus confounding many of the experts, and there have been sharp frosts at night. While snow in towns is chiefly a source of discomfort, we need scarcely remind our readers that in the garden this heavy mantle of snow is of great protective value when followed by severe frosts, and will probably preserve many shrubs and plants that otherwise would be killed. It is in the low-lying districts, where floods have occurred, that the losses are likely to be the most serious. On the morning of Boxing Day, while the snow was yet undisturbed, and from six to twelve inches thick, the world looked very beautiful, for snow, like the setting sun, adds beauty to the already beautiful, and turns dreary wastes and ugly habitations into exquisite pictures.

Patents in 1927.—It is very satisfactory to note that there will be an increase of over one thousand Patent Applications this year beyond those of 1926, and that it is the best year since 1922. Messrs. Rayner and Co., the well-known London Patent Agents, inform us that electrical inventions are largely in evidence, due, no doubt, to the Government scheme of electrification of the country. Chemistry runs into second place, many applications coming from Germany relating to dyes and colours. Synthetic silk, the wonder-child of the chemist, is being very largely experimented with by great English and foreign concerns, who have obtained numerous Patents. The many tools and appliances that are now required for easier and better work in the garden are well represented in the inventions and patents of 1927, and there is a general trade advance in many other important industries. The Improved Patent Office figures will greatly brighten the outlook for business in the New Year.

Narcissus Irish Queen.—The Daffodil sent to the Royal Horticultural Society's Trials by Mr. Watts under the name of "Mavourneen" and which received an Award of Merit this spring for garden decoration, has now (since that name is preoccupied) been named Irish Queen.

New Scotch Potatoes Registered.—The Board of Agriculture for Scotland announces that on the recommendation of the Synonym Committee it has registered the following new varieties of Potatoes, which have undergone the usual three-years' test, viz., Herald, raised by Messrs. McGill and Smith, Ayr, and Arran Banner, raised by Mr. Donald McKilvie, Lamlash, Arran. In the opinion of the Committee, Herald is superior to Sharpe's Express and Eclipse, although the Committee realises that this variety cannot supplant either Duke of York or Epicure; Arran Banner is recommended as a high-yielding early main-crop variety. The Committee also recommends that further extended trials of Doon Star be made in 1928 before an opinion is expressed as to whether or not it is worthy of registration. The following is the Board's description of the two varieties:—**Herald:** Maturity, first early. Tuber, oval to oblong; skin white; eyes shallow; flesh white; sprouts blue. Foliage: haulm, medium height to upright; main stems strong; leaflets light to medium green, broad, thin and cupped; terminal leaflet often tied, glossy. Flower

white; berries occasional.—**Arran Banner:** Maturity, early main-crop. Tuber, round pebble; skin white; flesh white; eyes shallow, saucer-shaped; sprouts pink. Foliage: haulm tall, upright; stems strong, slightly mottled purple, leaf markedly open; midrib of leaf slightly coloured at the bases of leaflet stalks; leaflet medium green, dull, slightly wrinkled; secondary leaflets often borne on leaflet stalks; terminal leaflet droops to perpendicular. Flower not observed; buds frequent, reddish-purple and hairy.

Mr. H. H. Brown.—A native of Durham, Mr. H. H. Brown started gardening at Shortley Grove, in that county, and, after three years became a journeyman gardener at the neighbouring estate of Shotley Park. Then, realising the value of experience in a good nursery he obtained employment in the nurseries of Messrs. Fisher, Son and Sibray, at Handsworth, Sheffield. This was in 1886, when the firm was, perhaps, better known in the north of England for the general excellence of their stock than in the south. To-day the high quality of the trees and shrubs grown by Messrs. Fisher,

MR. H. H. BROWN.

Son and Sibray are fully appreciated all over the country. Having, as he states, gained valuable experience at Handsworth, Mr. Brown moved to Osberton Manor Gardens, Notts., then famed for the growing of high-class fruit, and especially of Grapes. His next move was still further south and to Gunnersbury Park Gardens, where he became foreman of the fruit department. Thirty years ago Mr. Brown took over the charge of the well-known gardens at Castle Hill, Englefield Green. During this period Mr. Brown has managed the gardens with great success. Though only occasionally in the public eye, as when he has successfully shown Grapes of his growing at the R.H.S. Fruit Shows, he has quietly done good work, winning the admiration of his friends and deserving the satisfaction of his employers—the late C. C. Raphael, Esq., and the Hon. Mrs. H. Tufton.

King Arthur's Castle View for the Nation.—There is a special interest to horticulturists in the movement which is soon to be started to preserve Church Cliff, Tintagel, for public enjoyment, because one of the most generous supporters of the scheme is the Lord Lieutenant of the County, Mr. J. C. Williams, of Lanarth, who is widely known for his love of gardening. Church Cliff is about fifty acres in extent and overlooks the romantic ruins of King Arthur's Castle. The island rock itself is part of the Duchy of Cornwall, vested in the Prince of Wales, and so is safe from the builders. The present vicar of Tintagel, fearing for the future

of his glebe lands, has obtained the ready approval of the Ecclesiastical Commissioners to his proposal to part with them, and the National Trust will care for them for the public use for all time. Although chiefly of only potential building value, part of the area is generally considered to be the highest cultivated land in the west of England.

Disappearing Canadian Forests.—In a letter to the *Morning Post*, last week, Mr. Frank J. D. Barnjum, writing from Annapolis Royal, Nova Scotia, makes a strong appeal for the Canadian forests, which, he points out, are in a critical condition. The entire Dominion has now been opened up, and there are no more forest worlds for Canada to conquer. Vast quantities of pulp wood go south to enrich another country and leave the country of production all the poorer. In addition to the depletion thus caused, Mr. Barnjum refers to the official records which state that four-and-a-half times as much timber is destroyed in the Dominion by insects, fungi, winds and fire as by the axe—a truly alarming statement.

A National Sweet Pea Society for Holland.—We are interested to learn that lovers of the flower have formed a National Sweet Pea Society in Holland, very much on the lines of our own Society. The headquarters of the Dutch Society are at Leidschevaartweg, Haarlem. Mr. H. Carlée, of Haarlem, is the Chairman, and Mr. B. P. Vader, of Overveen, is the Secretary of this new special floral Society.

Glasgow Flower Shows, 1928.—It has now been definitely decided that the Autumn Flower Show to be held in the new Kelvin Hall, Glasgow, during the last week of August next, will be jointly promoted by the Corporation and the Glasgow and West of Scotland Horticultural Society. The Directors of the Scottish National Sweet Pea, Rose and Carnation Society have also decided to change the venue of their annual show to Kelvin Hall. Among the new prizes embodied in the schedule there is one of £5 offered by Messrs. C. C. Morse and Co., California, for the best bowl of their variety Pinkie.

Antwerp International Horticultural Exhibition, 1930.—We recently announced that the Antwerp Royal Horticultural Society had come to an arrangement with the sister societies of Ghent and Brussels by the terms of which the Antwerp Society will organise a great International Horticultural Exhibition in the spring of 1930, with the support of the Ghent and Brussels societies. This arrangement has recently been followed up by another made between the delegates of the Antwerp Society, represented by M. Emile Draps, President; R. Van Rysselberghe and J. Mulder, Secretaries, of the one part, and the members of the Provisional Horticultural Committee, with the Executive Committee of the 1930 exhibition in Liège, of the other part. The Liège delegation consisted of MM. Jean Sladden and Etienne Joiris, Administrators of the Liège Royal Horticultural Society; M. Charles Chevalier, Secretary; and M. Emile Coumont, Hon. President of the Ensival Royal Society. The gathering was unanimous in its decision to contribute to the Antwerp International Horticultural Exhibition, and to put forth its best efforts to make a success of this floral manifestation in 1930. In this way the whole Belgian horticultural world will be mobilised to celebrate with becoming éclat, the Centenary of the Declaration of the Independence of Belgium. The delegates were likewise in agreement in favouring a general exhibition of horticultural products in September, 1930, at Liège, to which Antwerp growers will render their generous support. As regards the temporary exhibitions, these will bear a regional character, and detailed arrangements will be made later on. It is now certain there will be an International Horticultural Exhibition at Antwerp in 1930, and it is expected that all Antwerp residents, particularly the many flower-lovers to be found in the city, will heartily support the initiative shown by the horticultural societies and experts.

Status for Versailles Ex-Students.—There have been great rejoicings—culminating in a banquet which took place on October 29—over the decision of the French Minister of Agriculture that students who have passed through the National Horticultural College at Versailles and taken their degree shall receive the title of "Horticultural Engineer" ("Ingénieur Horticole"). Some there are who regard this concession with contempt, and state that the title is a "label" of no value; but many of the ex-students, especially among the younger generation, highly appreciate the distinction accorded them.

Preservation of a Hampshire Beauty Spot.—The well-known Hampshire woodlands—Harmsworth Row and Eversdown Copse—which adjoin the Humble River between Botley and Southampton, were recently advertised for sale and a movement was started to preserve the woods and other lands from being built upon. The safety of the major portion is now assured, as the woods have been bought by Mr. and Mrs. Hugh Jenkyns and given to the National Trust "In happy memory of their daughter Priscilla."

Increasing Attendances at the Zoo.—Up to the end of November there had been 2,135,397 visitors to the Zoological Gardens, London. The receipts were £67,797, which show an increase of £7,513 when compared with the corresponding period of 1926, and an increase of £11,565 on the average of the previous five years.

Parisian Florists' Banquet.—On Sunday, December 4, the annual fête of the florists of Paris and environs took place. The banquet, at which a large company was present, including many ladies, was presided over by the Inspector General of Agriculture, M. Guillon, and the occasion was further honoured by the presence of M. Nombrot, Secretary of the National Horticultural Society; M. Sauvage, Hon. President of the Syndical Chamber; and M. Van de Weyer, President of the Belgian Florists' Association. Needless to say, the decorations were superb, the pillars of the hall being twined with Smilax and grouped with Palms and Azaleas, while the tables were decorated with Roses, Carnations and Lilies. Many speeches were made at the banquet, and the evening finished gaily with a dance.

Appointments for the Ensuing Week.—TUESDAY, JANUARY 3: Royal Horticultural Society's Committees meet. WEDNESDAY, JANUARY 4: Nottingham and Notts. Chrysanthemum Society meets. THURSDAY, JANUARY 5: Linnean Society meets; London Gardens Guild Lecture. FRIDAY, JANUARY 6: Accrington Chrysanthemum Society meets; Bridport Chrysanthemum Society meets; Dundee Horticultural Society's lecture. SATURDAY, JANUARY 7: Blackburn Horticultural Society's meeting and lecture.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Pear Beurré Gris d'Hiver Nouveau* or *Beurré de Luçon*.—This fine large Pear is, I think, calculated to form an important feature in our winter desserts. It seems to be of the race of the old Brown Beurré, Beurré Gris of the French; its fruit has nearly the same shape, but they are larger and generally covered with a thick coat of russet; it differs, however, widely from its type in the great merit of being fit for table from two to three months after Brown Beurrés are gone and forgotten; it is in season generally from the end of January till the middle or end of March; its flavour is peculiarly high; its flesh melting and very juicy, but liable in some soils to be a little gritty; it does not grow freely on the Quince, unless under glass, and is not hardy enough for a pyramid on the Pear stock, unless in very warm and sheltered situations, but it deserves a wall (a south-east, south, or west aspect would be most eligible), and ought to be in every good collection of Pears. *Thos. Rivers. Gard. Chron., December 25, 1852.*

Publication Received.—*Beautiful Flowers of Kashmir*, by Ethelbert Blatter; Vol. 1; John Bale, Sons and Danielsson, Ltd., Oxford House, Great Titchfield Street, W.1.; price 21/- net.

ORCHID NOTES AND GLEANINGS.

STENOGLOTTIS LONGIFOLIA.

ALTHOUGH the individual flowers are small, fine spikes of this cool-house Orchid are very useful and attractive. They appear from the end of October until well into the New Year, therefore they are most useful in maintaining a display of flowers during the darkest period of winter.

Stenoglottis longifolia is very easily cultivated, provided the plants are grown under favourable conditions. They delight in an airy position

BULB GARDEN.

SCILLA PERUVIANA

It was pleasant to observe such a favourable account of the Peruvian Squill as is given by *N. Wales*, on page 482. From it one gathers that your contributor does not experience the same difficulty as many do in obtaining regular annual bloom from *S. peruviana*. Like some other bulbous plants from warmer climes, it appears to miss the warmer seasons of its native land, and generally refrains from flowering after the first season. I have grown it and have seen it tried in other gardens, some of them

FIG. 248.—CYPRIPEDIUM WESTMINSTER.

R.H.S. Award of Merit, December 13. Flowers white, brown and yellow. Shown by Messrs. Black and Flory. (see p. 493).

in a cool house. After the flowering season is over, they generally lose many of their leaves, but this is not detrimental, for it allows the young basal growths more light and air. When the old growths are dying off the water supply should be reduced, but the roots should never be allowed to become dry.

So soon as the young growths are about to make new roots, they should be potted, and the best results are attained when each growth is potted separately. Being terrestrial Orchids, a compost of two parts good loam to one part of leaf-mould will be found suitable, adding plenty of sand to keep it porous. Use ordinary pots, and afford ample drainage.

After potting, afford water carefully until the plants are well-rooted, when they will need copious supplies.

Stenoglottis longifolia, like the closely allied *S. fimbriata*, is a native of Natal and has been in cultivation for many years. A.

in warmer localities than mine. It is possible that the lifting and dividing advocated by your contributor may have a good effect.

STERNBERGIAS IN SCOTLAND.

LIKE Sir Herbert Maxwell (p. 485), I shall be glad to learn of the flowering of the Sternbergias in northern gardens. They would be very pleasing if we could be sure they would flower with us. I have tried bulbs bought as *S. lutea*, *S. angustifolia* and *S. macrantha* at various times. What I found was that bulbs would generally flower the first year after planting, but the only one which might give a stray flower or two in after years was the one known as *S. angustifolia*. Bulbs of *S. macrantha* imported from Asia Minor bloomed splendidly the first season, but, so far as my memory serves, never again. One regrets having such a disappointing tale to tell. *S. Arnott.*

The Week's Work.

THE ORCHID HOUSES.

By J. T. BARKER, Dunstable, Bedfordshire.

Seasonable Remarks.—Another year has run its course, and although the past season has been far from an ideal one for many subjects, the cool Orchids have revelled in the dull, moist, cloudy conditions. After such a season, serious fluctuations of temperature should not be permitted, as immature plants suffer much more than those properly ripened. During this, the latter part of the year, we may look round and take stock of the season's work, sum up our successes and failures, see where we may improve the former and avoid the latter. At this season also much may be done to prepare for the busy season ahead. Peat and fibre may be prepared, crocks made ready, and a supply of Sphagnum-moss secured; in fact, everything that does not deteriorate by keeping may be dealt with. It is surprising what foresight and good management can accomplish in Orchid-growing. There is no excuse for slackness in the small matters suggested, for delays may mean the postponement of potting; meanwhile, the roots will have made so much progress that they cannot be potted without injury.

THE KITCHEN GARDEN.

By R. H. CROCKFORD, Gardener to THE RT. HON. LORD WAVERTREE, Horsley Hall, Gresford, N. Wales.

Broccoli.—Those who acted on the advice given earlier, and laid their Broccoli plants with their heads to the north, will now notice that the hearts are covered with their own leaves and protected from frost and snow. Should the weather prove excessively severe, a little Bracken or straw laid lightly over the bed will keep all secure. Where deep pits or frames can be spared, some of the most forward plants should be lifted and placed therein; cover the lights on frosty nights.

General.—Whenever the soil is sufficiently dry, advantage should be taken to run the hoe or scuffle between the rows of spring Cabbages, Spinach and Onions. See that all land drains are clear, otherwise the soil will soon become a sodden mass. During frosty weather keep the smother fire going and burn all rubbish which comes to hand, but take care that the useful ash is placed under cover. So much as fifteen per cent. to seventeen per cent. of potash has been found in the dry ash from green trimmings, but wet ash soon loses this fertiliser.

Retrospect.—On the whole, kitchen garden crops have been abundant and good during the year now closing, and they were grown with far less labour than would have been the case had the season been hot and dry.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to SIR CHARLES NALL-CAIN, Broomfield Hall, Hertfordshire.

Spiraeas.—For early forcing, retarded clumps will be found to give excellent results. The clumps should be potted in the smallest receptacles that will accommodate them without injury to the roots. They should not be subjected to strong heat immediately after potting; just cover the crowns with moss and stand them under a stage in the greenhouse until they commence to grow freely, when they may be given warmer quarters and more light.

General Remarks.—Continue the propagation of Chrysanthemums as cuttings become available. Cuttings inserted this month are for the production of large blooms; next month will be more suitable for rooting the decorative and Single varieties, while those that are grown to produce

the latest flowers possible, a later date is still more suitable. The pots, soil and frames for the reception of the cuttings should be prepared. Undue flagging should be prevented. Continue to cut the plants down as they pass out of flower and place them in a cool house. For the propagation of Perpetual Carnations, choose cuttings from vigorous plants. Protect the occupants of cold frames during severe weather, but do not coddle the plants growing in cold frames; keep them sturdy and healthy by ventilating the frame on every possible occasion, remove dead leaves and guard against the ravages of slugs.

Bulbs.—An examination of the bulbs that are still in their plunging material should be made each week from now onwards, removing all those that have made sufficient roots and growth. Keep them in the dark for several days, then gradually expose them to the light. The season is now approaching when forced bulbs have to be relied upon to supply cut flowers, and no gain, and probably disappointment, will result if too hasty forcing is attempted. The bulbs should be introduced into gentle warmth at first, increasing the temperature gradually.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to COLONEL SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Strawberries.—The mild weather during the early part of this month encouraged early batches of Strawberries to push up their flower spikes. When these approach the flowering stage they should be moved to the lightest and most airy part of the house. In a Strawberry house the earliest plants invariably have the best position, but few have this accommodation. Fresh air is imperative from the time they are introduced until the fruits begin to swell. Excessive fire-heat or anything approaching dry heat is most injurious, therefore, endeavour to coax the plants into flower with as little artificial heat as possible. Vigorous flowers may set without artificial aid, but a camel-hair brush should be used when pollen is plentiful in the middle of the day. Careful watering throughout their early stages of development is most important; although Strawberries delight in plenty of root moisture, serious mischief may be done by giving too much when the plants are in flower. Examine each plant, keep the roots in a moist state, but not wet. Another matter that must not be overlooked is mild fumigation at short intervals prior to the opening of the first flower. Introduce fresh batches according to the stock and the demand.

Figs.—Figs trees in successional houses may be put in readiness, as previously advised, cleaning and top-dressing them as may be required; they will then be ready for starting at any period of the New Year.

HARDY FRUIT GARDEN.

By H. MARKHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet, Middlesex.

Winter Dressing for Fruit Trees.—The present is a suitable time for cleansing trees infested with moss and insects. Where the trunks and main stems are thickly coated with moss, scrape them with a small hoe and afterwards apply a good dressing of lime wash, dusting the smaller wood and branches with soot and lime mixed. Spraying with caustic soda, applied according to the directions given on each tin, is also effectual, as it not only destroys the insects but cleanses the trees of moss and leaves the bark bright and clean.

Nuts.—A few of the best varieties of Nuts should be grown in all gardens where there is space. Nuts will thrive in places not suitable for some other kinds of fruits, so long as the drainage is satisfactory. A moderately porous soil will suit them if the position is not too exposed. Large trees in full bearing should be manured occasionally.

Training.—The best form for a Nut bush is the basin shape, and its height need not exceed eight feet. Those who may wish to raise a few useful trees should plant young, strong suckers, and when these are well established prune them back to fifteen inches above the ground level. The young growths should be carefully selected and trained to form the future bush. Remove strong, useless wood, and prune old trees so as to encourage plenty of young twiggy, fruiting wood all along the branches.

THE FLOWER GARDEN.

By JOHN COUTTS, Assistant Curator, Royal Botanic Gardens, Kew.

Roses.—Newly-planted Roses, as well as established plants, should be examined frequently, especially after heavy rains and high winds, as they may be blown about and loosened and water then collects round the stems; when this happens, the ground should be forked up about them before any attempt is made to tread them in again. In some cases it may be necessary to lift and replant. All plants likely to be blown about should be staked, and even if this was done during the autumn, there may be plants requiring attention.

Snowstorms.—Over the greater part of the country snowstorms may cause a good deal of damage among certain Conifers; Cedars suffer very much, and large limbs are sometimes broken by the weight of the snow. Much damage may be averted if the snow is shaken off. In the north, where heavy falls of snow may be expected, long poles should always be kept in readiness for this work. Heavy falls of snow generally entail a considerable amount of labour in clearing paths and drives; for this purpose suitable tools should be kept handy. While light falls may be removed by the aid of brooms, heavier falls may entail the use of some form of snow plough or shovel, and for his purpose large, light, wooden shovels are best. Ponds and lakes may also have to be swept and cleaned for skating or curling.

FOR NORTHERN GARDENERS.

By A. T. HARRISON, Gardener to the MARQUIS OF AILSA, Culzean Castle, Maybole, Ayrshire.

Preparations for Seed-sowing.—Preparations for seed-sowing should always be made in good time, and supplies of loam, leaf-soil, sand, etc., placed under cover so that they may become drier than if left out-of-doors. Boxes and seed-pans should also be examined, and where the supply may have become depleted, fresh ones should be ordered or made at once. During stormy weather, dirty pots may be washed, dried, and stored in their respective sizes, and a rough calculation made as to probable requirements. Even the crocks, which, perhaps, receive less attention than most accessories, should be washed and sorted into various sizes, to facilitate their use when the busy time comes. Stakes should be cleansed and afterwards tied up into suitable bundles.

Seed Potatoes and Other Roots.—Examine the boxes containing seed Potatoes, and remove all bad or diseased specimens. The earliest varieties seldom fall victims to the Potato disease, as they are out of the soil before this fungus develops. These are now sprouting freely and should be allowed plenty of light and air to keep the sprouts from becoming drawn, always taking the necessary precautions to protect them during frosty weather. Ware Potatoes stored under cover should also be turned over and have their sprouts removed so as to extend their season of usefulness.

Seed Catalogues.—These are now arriving, and quite a profitable way of spending an evening is to read some of them and make a note of any improved forms which the various firms have to offer. Progress is attained only by trying something new each year, and while it is, perhaps, necessary to take the glowing accounts of novelties with the proverbial "grain of salt," there is no doubt that many improvements in vegetables and flowers appear annually.

INDOOR PLANTS.

PRIMULAS.

DOUBLE Primulas are fine subjects for conservatory and house decorations, but their cultivation has decreased during recent years. Formerly, remarkably fine plants were on view at many of the autumn exhibitions. The specimens carried a wealth of bloom and abundance of healthy foliage. These plants were largely propagated from cuttings and from layers. The cuttings were inserted in small pots filled with light, sandy soil and placed in moderate heat.

A successful method of increasing the stock is by layering. So soon as the plants have finished flowering, remove a few of the basal leaves, partly sever the crowns with a sharp knife, and pile up a mound of fine soil and coconut fibre about the base of the plant. The soil should be kept moist; a close atmosphere is also favourable to quick root action. So soon as roots are formed, completely sever the crowns and place each one in a small pot. Excellent double varieties may be raised from seeds.

The old double white Primula produces abundance of useful flowers during the winter, and a compost of good fibrous loam, thoroughly decomposed manure, and sharp sand, suits it. A light position and an intermediate temperature should be provided, and when the pots are well filled with roots, soot-water and weak liquid manure are beneficial.

The free-flowering Primula kewensis is a most useful plant for the conservatory during the winter and spring. The bright yellow, fragrant flowers are produced very freely. Seeds may be sown from April to June. This plant thrives in a light, open soil.

The Abyssinian Primrose, Primula verticillata, with sweetly-scented, yellow flowers and grey, downy leaves, is a most attractive plant and worthy of extended cultivation in pots. Both P. kewensis and P. verticillata may be grown in cool pits and they provide a colour that is lacking in forms of P. sinensis. The association of blue Cinerarias with the Abyssinian Primrose is very effective. C. Ruse.

HIPPEASTRUMS.

Most of the large-flowering Hippeastrums will be at rest and stored on shelves where they are kept free from frost and drip, but some of the species may be had in flower during the winter months and form a useful addition to our stock of winter-flowering subjects. H. aulicum is now in flower, its bright scarlet trumpets lasting well in the dull, short days, while its bold foliage makes a splendid foil to the stately, upright spikes. This species is propagated easily by division, and when well established will remain in good health in a comparatively small pot for years, only requiring ample supplies of water and liquid manure.

TIBOUCHINA SEMIDECANDRA.

SOME two-year-old plants of this native of Brazil, formerly known as Pleroma, have made a wonderful show for the past few weeks in an intermediate house, their rich, deep, violet-purple flowers, borne in the greatest profusion, making a wonderful display of colour amongst the other occupants—mostly foliage plants.

The plants referred to are growing in eight-inch pots, and were accommodated for the most part of the summer months in a cold greenhouse, and only when it became evident that they were unlikely to develop their flowers entirely without heat were they removed to more comfortable quarters.

Cuttings made from young side-shoots are easily rooted, and if inserted at an early date and grown on, will make useful plants in six-inch pots for next winter's display, but it is the older and consequently larger plants of a second year's growth that become thoroughly decorative and useful. One or two flowering branches make a handsome display in a vase, the silvery, down-covered foliage being a perfect foil to the purple flowers. A. T. Harrison.

TREES AND SHRUBS.

BITTER ORANGES AT PORLOCK.

I ENCLOSE a photograph (Fig. 249) of a Bitter Orange bush fruiting in this garden. It is planted at the foot of the garden wall and receives shelter only during exceptionally stormy weather. We have several other specimens, also planted out in the open, and they have been there several years. They fruit well, and we use the fruits for marmalade, as recorded in my note that appeared on page 493. G. W. W. Blathwayt, West Porlock House, Porlock, Somersetshire.

HARDY FLOWER BORDER.

A LOST FORM OF ANEMONE APENNINA.

IN 1890 or 1891, a few folk who admired alpine flowers obtained from the Abercorn Nurseries of Messrs. Munro and Ferguson, at Piershill,

FIG. 249.—BITTER ORANGES FRUITING IN THE OPEN AT PORLOCK, SOMERSETSHIRE.

Edinburgh—a long extinct firm, whose catalogue, dated 1889, I still possess—a blue Anemone which we greatly admired. It was sold as A. blanda; it was not that species, but appeared to be a very fine form of A. apennina. I grew it for a number of years, but lost it during the period of the Great War, when official duties prevented me from attending to my plants as usual.

I had not seen it elsewhere for some time previous to that, and was surprised and interested to receive flowers and leaves from the late Messrs. Cocker, of Aberdeen, with a letter informing me that this Anemone was growing in one of their borders, and asking me if I could give them its name. As the nursery of the latter firm is now disposed of and I have never heard of this Anemone since, I therefore fear that it is lost.

While this "Anemone incognita," as I may term it, presented a similar appearance to some of the best forms of A. blanda, it flowered at the same time as A. apennina, and in general appearance had a close resemblance to that species, with the same rooting habit. It was of a lovely shade of blue, and the flowers, which were freely borne, were more symmetrical than those of the ordinary forms of A. apennina or even A. blanda. Up to the present, I have not been able to trace it again, but this note may lead to someone giving information regarding a charming flower of a delightful race.

MONTBRETIA (OR TRITONIA) ROSEA.

In thinking over the plants which, either alone or by union with other species, might be made of greater value for the garden, one cannot but remember Montbretia rosea, which, by-the-way, we are told should now be called Tritonia rosea. So much has been done in the way of development in the other Montbretias that it appears probable that M. rosea might yield excellent results, either by seedling-raising and selection or by hybridisation. It is quite a neat and graceful species, without any of the stiffness which is almost the only defect of the modern Montbretia, and its flowers are of a pleasing rose. I have found it hardier than some of the newer Montbretias.

Seedling raising might yield us flowers with larger blooms, or, still more desirable, of more pronounced colouring, but, as it is, M. rosea is quite a good garden plant of about eighteen inches high, with a number of pretty, rose flowers. M. rosea is a cheap plant and a few corms may be purchased for a small cost, and planted in spring, preferably in clumps, about

two inches deep, and the same distance apart. M. rosea increases satisfactorily in ordinary garden loam, but in heavy soil a little sand should be placed below and round the corms. March is quite a good month in which to plant this pretty subject. S. Arnott.

ROSE GARDEN.

ROSA LAWRENCEANA.

ALTHOUGH its correct name appears to be Rosa indica minima, the varieties of the Rose known as R. Lawrenceana are exquisitely pretty. This autumn, I much admired a colony of a double-flowered variety growing on the rock garden; the flowers were a good, deep rose colour, the small blossoms very double, and the miniature bush compact and rounded. The double forms, collectively, are often called "Fairy Roses," a not inapt description. R. i. minima is figured in Bot. Mag., t. 1,762, under the name of R. semperflorens minima, and in Bot. Reg., 538, as R. Lawrenceana.

These little Roses enjoy a well-drained, sunny position and might well be more frequently employed on rock gardens and in borders; they are also excellent pot plants. Ralph E. Arnold.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C. 2.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc. but they cannot be responsible for loss or injury.

Letters for Publication as well as specimens of plants for naming, should be addressed to the EDITORS, 5, Tavistock Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired the signature will not be printed, but kept as a guarantee of good faith.

Urgent Communications.—If sent by telegraph, these should be addressed "Gard. Chron." Rand; or by telephone, to Gerrard, 1543.

Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

FIG. 250.—A HALF-FROZEN MOUNTAIN STREAM.

MR. F. KINGDON WARD'S NINTH EXPEDITION IN ASIA.*

XXII.—THE LAST WEEK.

EVEN while we were at the yak camp the fine spell of weather broke up, mist and rain came down, and when we awoke on October 23, the high peaks above 12,000 feet were white with the first film of snow; but this did not remain. Meanwhile, the crisp, keen weather of the past week had hardened the Rhododendron capsules in the alpine region; but whereas the small alpine species ripen their seeds in from three to four months, those of the temperate forest may take six or nine months over the business.

When we returned to the village on the 22nd, we found the Tibetans reaping the last of the meadow grass, and yak trampling about all over the place. There were still a few leeches on active service, but the cutting of the meadow had practically immobilised them. The river had fallen a lot, and it was possible to cross the flimsy, temporary bridge in comparative safety.

I had several days' work to do, including packing my seeds, an ascent to the high ridge after the 'Silver' Barberry and two or three Rhododendrons, and a descent to the low ridge for the 'Fox brush' Acer and the large-leaved 'Irroratum' Rhododendron; but the 23rd was spent doing staff work, paying the coolies, taking stock of rations, and so forth. I was anxious, if possible, to get away before the end of October, as I feared my coolies would not face the pass if I delayed too long; after all, they had to get back, I had not. It was clear that no reliance was to be placed on the weather. A spell of four or five cloudless days would be followed by a storm which might last a week. There was a new moon on November 3. The weather in the mountains often changes with the change of the moon—this may be a mere superstition, but most of us live by superstitions. Should I wait till November 3, or try to get away on October 29, so as to cross

the pass on the last day of the month? It all depended on what the weather was going to do in the next few days—a 'change' might mean a change for the bad! In the end I decided to cross the pass on October 31, which happened to be a bad decision.

The Tibetans were quite unreliable, so I decided to dispense with them altogether, and trust to my Tarons and Lisus, even though

FIG. 251.—LISU TABOO AGAINST SICK PERSONS ENTERING A HEALTHY VILLAGE.

they had little more than a rag of clothing apiece. I had twenty of these folk on the spot, and by giving them a little food and money down, with the promise of double wages for the journey to the Lohit, I kept them by me until we were ready to start.

On October 24, I again tackled the limestone ridge, which was a fairly severe climb. We collected seed of all the good things—Silver Barberry, Cotoneaster, Ilex, Rhododendrons, Enkianthus and a Vaccinium. The Barberry had blue-black, Pear-shaped fruits, like a Mahonia, which was a pity. The leaves of the Enkianthus had turned scarlet, the 'Thomsoni' Rhododendron was bursting into pink flowers, but yielded only a dozen capsules, and the Cotoneaster, with its long ranks of coral-red berries, was splendid. There were even a few flowers on the ridge, including Aster and Lonicera. I ascended higher than we had been before, but the growth was so thick, even on the ridge, and there was so much to collect, that it was impossible to reach the summit. As it was, darkness had fallen before we got back.

The only other long excursion I made was down to the Rhododendron ridge, where I found many of the epiphytic Orchids, including a Coelogyne and the curious, gloomy-looking Dendrobium triste, in flower. The Acer still trailed its long fox brushes; the plant recalls A. Henryi, but it has simple, entire leaves, with long drip-tip, instead of compound leaves. A curious tree which had already puzzled me was in flower here. It is deciduous and has large leaves very like some of the Magnolias. Its fruits, like large, brown Walnuts, I had mistaken in the spring for flower buds (seen high up, they looked not unlike Magnolia buds), but now I discovered that they were in reality five-chambered, Rosaceous fruits, and the tree, which was leafless, and in full bloom, was a glorious sight, crowded with huge, scented, inflorescences, cream-coloured and fragrant as Meadowsweet. I secured a number of fruits, but found that more than half the seeds had been destroyed by grubs. Whatever the tree was, it was distinctly uncommon, a feature of the lower temperate rain forest round about 6,000 to 7,000 feet (rather lower than Magnolia rostrata), with Pinus excelsa, Quercus sp., Rhododendron Mackenzianum, etc. It seemed to prefer the exposed rocky ridges, which, although covered with forest (or because of it), were almost unscalable; the flanks were too thickly covered with Bamboo for trees to get much chance.

Meanwhile, my hut was a litter of drying seeds, which were being packed and catalogued so fast as possible. Before sealing up any packet I made sure that the bulk of the seed was fertile; that is to say, I scrutinised it through a pocket lens, and to pass the test, the seeds had to be (1) plump; (2) the right healthy colour, and (3) properly marked with the correct 'chop'—ridges, tubercles, pits or whatever nature chooses to bestow. One soon gets to know what ripe, fertile seeds ought to look like, and if they were not up to sample, I threw them away.

October 28 was a glorious, cloudless day, which in the mountains is often only the lull before the storm. I made final preparations for a start next day, calling up all the coolies and telling them to parade early. I decided to leave the chokara behind, and take only my two Nung coolies, although it was difficult to converse with them as we had no common tongue; but the pyada did know some Burmese—probably as much as the chokara knew Hindustani. At the eleventh hour, I formulated a plan to return to Fort Hertz and cross to the Lohit by the Krong-jong pass (under 10,000 feet), if I failed to get over the Diphuk La; but if I once crossed the latter I was determined to go on, come what might. I had several objects in view. There was, first of all, the necessity for collecting seeds of the Rhododendrons and other shrubs found in the Di Chu valley in July. But even more important was the finding of a good route to, and base camp for, tackling the mysterious country which lies between the Lohit and the Tsangpo gorge. This country was only to be approached via the Lohit valley, and that in turn could only conveniently be reached from Sadiya.

* The previous articles on Mr. Kingdon Ward's Ninth Expedition in Asia were published in our issues of August 14, 28, October 9 and November 20, 1926, and January 1, February 19, March 5, 19, April 9, 30, June 4, 18, July 30, August 20, September 10, October 1, 15, November 6, 19, and December 3, 17, 1927.

But since the days of Dr. Griffith, nearly a century ago, no botanist had succeeded in basing an expedition on Sadiya, and my own requests had been refused. Therefore the only thing to do was to appear in Sadiya, by permis-

sion, from the direction in which it was proposed to explore, and arrange things with Powerful People quietly on the spot, so that I could return later. Hence the vital necessity of crossing by the Diphuk La rather than by the Krong-jong, if it were humanly possible. As regards time, as already pointed out, I was thirty-five marches from Myitkyina, but only twenty-three from Sadiya, so that, provided I was not held up anywhere, I actually saved twelve days by taking the Assam route. Of course, in practice I did not, and could not, have saved twelve days on so difficult a route; but when we started for Sadiya on October 29, little did I think that it was going to take us more than six weeks to get there.

As anticipated, the brilliance of the 28th was a warning, to be succeeded by drizzling rain after midday on the 29th. We ascended to the yak camp, and became enveloped in cloud; snow was falling a little higher up. It rained all night, and the morning of the 30th was thick. The coolies shivered and shook their heads, but there was nothing to be done now except make a bolt for the pass. We started in pouring rain, and were wet through and miserably cold by the time we reached my hut at 11,000 feet. Here we halted for a meal. The coolies proposed to stay the night, but I urged them to go on and hope for better things, so we went on to the last yak camp, at 12,000 feet. And that night it snowed again and in the early morning it began to clear. It was very cold for the coolies, but we had good cover and plenty of firewood; nevertheless, everyone looked blue after breakfast, until the winter sun peeped over the ridge and began to melt the snow. We could see the pass now, and it was apparently almost void of snow, which was melting fast, as the warm air began to come up from the Burmese jungle. Also the sky was clearing and the sun struggling out.

I got the coolies off, after lightening the loads so much as possible, and then went here and there to collect seeds. Even so, I reached the pass some time before the coolies, who had sat down in a body a few hundred feet from the top. Immediately I reached the summit I had a shock. An icy blast was blowing straight off the Tibetan plateau. The precipitous descent on the other side was banked fathoms deep with drifted snow, and looking down the valley, beyond the lake, one saw nothing but snow,

snow everywhere, with never even a tree to welcome one with thoughts of a fire. It was a most disheartening spectacle. Would the coolies face it? I saw them toiling up below and decided to risk it; better to go ahead and stamp

a trail. Down I plunged, floundering knee-deep, then waist deep, in the drifts, but making a good trail. At last I reached the lake, and halted to collect seeds; looking back I could see figures descending the great white face.

About two hours later, seven of us were gathered by the lower lake, not by any means out of the snow, but at any rate, in sight of timber.

us; but of the sixteen Tarons, not one appeared, nor did they come in that night.

On taking stock of our property, I found that my bedding was present, and a box containing some of my specimens; but we had nothing to eat. We lit a large fire, and settled down in the snow to wait for day light and get what sleep we could in the meantime; I felt certain that darkness had overtaken the Taron contingent before they were able to reach our camp (for we had made a rather long march, considering that the going in the snow was none too easy), and that they had settled down for the night at the first clump of Fir trees, about an hour's climb from where we were. F. Kingdon Ward.

NOTES FROM A WELSH GARDEN.

COTONEASTERS have borne a wonderful crop of berries this season, and there can be few if any, genera which will give such a good return in ornamental fruits for so long a period as this one. Beginning with *C. adpressa* var. *praecox*, with large red berries coloured early in August, even a moderate collection will maintain a display until February. *C. pannosa*, for example, is only now (mid-December) beginning to look its best, and the beautiful, soft, grey-green foliage of this handsome species is exceedingly attractive when every elegantly sweeping bough is hung with clusters of blood-crimson fruits.

Taking both leaf-colour and berrying into consideration, *C. horizontalis* is still, I think, without a rival in its own way. Grown in bush form in the open, with plenty of space for development, this fine old shrub can be remarkably effective. The foliage assumes a rich and glossy plum-purple hue, while the brilliant scarlet berries will (in the absence of birds and mice) adorn the fish-bone branches until Christmas. In this garden the crop is very soon cleared, but, oddly enough, a form of *C. horizontalis* which is in every way as good as the type never loses a berry. This shrub is grown in the same way as the common one, save that it is covering a gentle slope, whereas the other is on the flat. Yet, while the species was stripped so soon as the

FIG. 253.—RHODODENDRON SP. (§ HELIOPSIS) AND ABIES FOREST.

With my two Nung servants I pushed ahead to find a suitable camping ground, and light a fire, and struggling on through the still deep snow, we eventually pulled up on the flat, where two streams joined, and selected a site amongst a screen of Rhododendrons. Here the four coolies—two Lisus and two Nungs joined

berries coloured, this variety is still covered with fruits which it will retain until hard frost comes. Here, then, is a pretty problem for the naturalist as well as for the scientific gardener.

Owing to the wet summer and autumn, most of the Berberises which one looks to for berry and leaf tints were late in colouring. Or

perhaps, it would be nearer the truth to say that they were later than usual, for I am beginning to feel that these shrubs—the newer Chinese species and hybrids—would be much more valuable if they could be induced to ripen their crop a few weeks earlier than is their habit. For the last two or three seasons they have scarcely attained their full beauty before a November frost has arrived to destroy it; and it does not require many degrees of frost to reduce the lovely, translucent, pink berries of *B. polyantha*, *B. Prattii* or *B. aggregata* to pulpy masses of a harsh, unpleasant red; and the foliage colour of such of these is even more ephemeral in such autumns as we have

leafage will be almost as bright as its autumnal tint, and few shrubs of the kind are more delightful against a dark background during those two seasons.

The *Grevilleas* never fail in their cheerfulness at this time of year. Though we had enough frost last month to cut down the big *Gunneras* and make the *Osmundas* turn colour in a single night, these courageous Australian shrubs suffered no harm. To-day (December 15), *G. rosmarinifolia* is bearing quantities of its crimson flowers. *G. sulphurea* is tufted with its jaunty cockades in ivory-yellow, and the grey-green foliage of *G. alpina* is flecked with a keen rose-pink. These hearty shrubs, growing quite

justified, this hybrid is an invaluable plant. Its fresh, shell-pink colour is singularly beautiful, it is good in habit, hard as nails, very amenable to almost any soil or situation, and it flowers bountifully at the dreariest season of the year. Because of these admirable attributes there are a hundred choicer, more costly, shrubs that I would willingly forego for *E. darleyensis*.

It is from this time onwards, throughout the winter, that many grey- or golden-leaved evergreens become most attractive. Some of the *Senecios*, such as *S. laxifolius*, *S. Greyi* and *S. Munroana* have their foliage more densely felted with white than they had during summer; and the contrast between the green upper surfaces and the creamy-white underparts in such species as *S. rotundifolia* is never so strongly marked as it is to-day. That excellent little Scotch Pine, *Pinus sylvestris aurea*, offers another example. A few weeks ago it was wearing its summer green; now, every needle is gleaming like polished brass. In the *Oleasters* the same process is noted, whether the predominating tint is silver or gold, or both. The large-leaved *Elaeagnus macrophylla*, perhaps the handsomest of the genus, is one of these. In these species the young foliage and unripened wood, as well as the under-surfaces of the leaves, are silvered with a metallic lustre. Even the little, nodding, tubular blossoms, which are now announcing their presence by imparting a Vanilla-like fragrance to the wintry air, are sheathed in silvery scales.

Whether *Symphoricarpus orbiculatus* blooms and fruits in other gardens I do not know, but I cannot remember ever having seen its purple berries in this part of the country. Like a good many American shrubs, our summers are rarely sunny enough for it. Here I only grow *S. o. var. variegata*, a quaint, little shrub which is accorded hospitality on sentimental grounds, since it is one of those ornaments of old gardens which seem to be uncommon. With us the variety is particularly evergreen, carrying a few leaves throughout the winter. It has never shown any inclination towards suckering.

A spell of mild weather, even so late as this, induces that wonderful plant, *Gentiana sino-ornata*, to expand the last of its buds, and it is odd to see these sapphire trumpets bidding farewell to the old year while, in the same bed, *Winter Aconites* are announcing the advent the new. Save for these, there would be little of flower colour left in the lower and damper parts of the garden. But the *Kaempfer Irises* are slashed with vivid yellow, the tall, upright stems of the *Lythrums* are a rich red-brown, and the seed-heads of *Astilbes* and herbaceous *Spiraeas* glow with warm shades of russet and umber. These may suggest that a wet autumn has thrown seasonable work into arrears, or they may afford a useful excuse for neglect. But as there is no avoiding the fact that such things have their value in the garden during the darkest hours of the year, their removal is deferred so long as possible. *A. T. Johnson, Ro Wen, Conway, North Wales.*

FIG. 254.—CANE SUSPENSION BRIDGE; HEADQUARTERS OF THE IRRAWADDY.

had in recent years. *B. dictyophylla* is a notable exception, for if it cannot compare with some of its allies as a fruiting species its foliage is wonderfully brilliant and, what is more, it is retained well into the winter.

Whether one regards it as a species or not, *Spiraea japonica var. alba* (*S. callosa alba*) is as distinct at this season as at any other, every leaf being rich yellow. This foliage is, moreover, much more persistent than that of the other varieties of *S. japonica* grown here. *Neillia* (*Spiraea*) *opulifolia* is a shrub of charming habit which also colours a really good yellow and retains its foliage until the later autumn. If the golden-leaved form, *N. o. var. lutea*, is grown, the spring

in the open on a Heath slope, have never given me the slightest cause for anxiety during the hardest winters.

Erica darleyensis had its first flowers fully open by the third week of November. As *Daboecia polifolia alba* was in bloom at the time—and it still is—these two serve to complete the cycle of the Heath garden's year. They join-up, as it were, the ends of that annual chain of blossom which even a moderate collection of Heaths will maintain unbroken throughout every month of the twelve. *E. darleyensis* may not be so fine a plant as either of its parents, *E. carnea* and *E. mediterranea*, but even supposing that such comparisons were reasonable and

IDEAL GARDENS AND PLANT LORE.

THE GARDEN OF THE MADONNA.

(Concluded from page 509.)

WHILE we shall be very careful how we introduce the *Convolvulus* into our garden, we shall certainly wish to find it a place, not only because of its handsome blossoms, but because they bear the very appropriate name of Our Lady's Nightcap. This is much more pleasing, though not more suggestive than the English name which is represented in German by *Teufels-darm*, a term which is also applied in both countries to the Dodder, and for the same reason. These plants belong also to the same Order (*Convolvulaceae*). Among the *Boraginaceae* we find the well-known Lungwort or *Pulmonaria* with its spotted leaves. This is in Germany *Unser Lieben Frauen Milchkraut*, and bears with us such names as *Mary's Tears*, *Lady's Pincushion*, *Lady's Milkwort* and *Lady's*

Milkmaid. To what has already been said respecting the latter term we may add one other interesting item of plant-lore. Under Virgin Mary's Milk Drops, Mr. Britten quotes the following from a letter by Dr. T. Smart of Salisbury:—

"I had an old woman weeding in my garden, and proposed to her to turn out a plant or two of it (Pulmonaria), to which she strongly objected, and said, 'Do 'ee know, Sir, what they white spots be?' 'No, I don't.' 'Why, they be the Virgin Mary's milk! so don't 'ee turn 'em out, for it would be very unlucky!'"

With reference to the name Mary's Tears, Miss E. M. Payne writes from Dorset that it comes from a legend:—"That some tears from the Virgin Mary, falling on the leaves of that plant, occasioned the white blotches on them; and that from her excessive weeping one eye which before was blue became red, in consequence of which the plant has since borne flowers of the two colours."

It is a thousand pities that the Forget-me-not, so far as I am aware, has not any association with Mary, and must therefore be excluded from our garden of Madonna blooms. All the members of the Order Solanaceae are of too sinister and poisonous a nature to find a place here, so we pass on to the Scrophulariaceae. Among the Mulleins we find that one is dedicated to Mary under the names Virgin Mary's Candle and Our Lady's Foxglove, names which find their counterpart in the German Frauenkerze or Kerse, Marienkerzen, Frauachunkla and Marienrosen. The Foxglove is Our Lady's Glove or Thimble, a name which is also given to the blossoms of the Campanula, Harebell or Bluebell.

We are glad to be able to introduce our Garden Mint (*Mentha Viridis*, L.) here, since it is associated with the Nativity under the name Sage of Bethlem, while in Germany it is called Unser Frauen Minze, and another species is named Marienmynte. Among the Primulas we find more than one which has an association with Madonna. Such names as Our Lady's Keys and Lady's Fingers are applied to the Oxlip and Cowslip, agreeing with such German names as Frauenschühli, Fraulischlössli, and Fruabluamli, where the final syllable is diminutive, or a sign of tender feeling and affection. Thrift (*Armeria*) as we have seen, is Our Lady's Cushion or Pincushion, and the Persicary (*Polygonum Persicaria*) is the Virgin Mary's Pinchweed. Mr. Britten who gives this in his Dictionary of English Plant Names (p. 481-2) quotes my original account, and confirms it by a reference to *Notes and Queries*. In Oxfordshire, I heard (at Fritwell) from a native, in 1883, the legend that the Virgin used it to make an unguent, but on one occasion she sought it in vain.

"She could not find in time of need,
And so she pinched it for a weed."

Ever since the leaf has borne a mark in the centre showing where the thumb of the Virgin pressed it. The plant grows freely in neglected gardens; it may now be given a place of honour, the more so as this, or a closely allied species, is named Marienkrud (Kraut) in Altmark.

When we pass to the Monocotyledons we find several which belong to our Madonna Garden. Best-known of all, probably, is the Lady's Slipper, or *Cypripedium*. This beautiful Orchid is now known in many forms, the gardener's art having brought it to a very high state of perfection. Another Orchid (*Spiranthes*) bears the name of Lady's Tresses. Mariendrehen is a German synonym for the latter, while for the former we have such popular forms as Frauenschühli, Frauenschüh with diminutives, and Frauschuckelblume on the one hand, and Marienschuh, Marienschoiken, with variants, on the other. The Snowdrop is of old dedicated to the Holy Mother, and is often known as Fair Maid of February. Tradition affirms that it blooms on Candlemas Day, which is the festival of the Presentation of Christ in the Temple. On the day of the Purification of the Virgin Mary her image is removed from the altar and Snowdrops strewn over the vacant place. Hence it is called Purification Flower and Candlemas Bells. The Lily-of-the-Valley is our Lady's Tears, and Solomon's Seal is sometimes regarded as a Madonna flower, bearing the name of Lady's

Seal, the German Mariensiegel, while the Snowdrop is Marienschelle, or Marienglöckchen, and Narcissus, the Lily of Mary. The Star of Bethlehem can hardly be denied a place here, and a few other plants belonging to this group might rightly claim inclusion.

Among grasses, we have the Feather Grass (*Stipa pennata*, L.), "a beautiful plant with remarkably long awns, common in gardens," as Babbington's *Flora* remarks. In German it is Marienflachs, which recalls the English Lady's Lint, a name for Stitchwort. The variegated form of Canary Grass (*Phalaris arundinacea*, L.) is known in Cheshire and Salop as Lady Grass, but this may be in allusion to its graceful form, and not to the Madonna. It is also called Lady's Ribands and Lady's Grass. But Lady's Hair, as a name for the Doddering or Quaking Grass (*Briza*) is genuine. Gerarde writes of it as Our Ladie's Hair, a name which is also given to the Maidenhair Fern. And this brings us to notice that in "Denmark, Norway and Iceland they give the name of Mariengras (Herb of Mary) to different Ferns, and in those countries Mary often replaces the Goddess Freyja, the Venus of the North, in the names of flowers."

In conclusion, I may quote from my note book under Lady Locket. "In Derbyshire, when the children gather the Lady's Smock, they sing:—

Lady Locket lost her pocket
In a shower of rain,
Milner fun it, Milner grun it,
In a peck o' grain."

Milner, of course, is the miller, while "fun" and "grun" stand for found and ground. *Hilderic Friend*.

NOTICES OF BOOKS.

The Beginner's Garden.*

THIS book has been compiled for the benefit of the garden novice of the United States of America. We write "compiled" advisedly, because Mrs. Francis King, in her preface, makes due acknowledgments to five current periodicals. But a book is none the worse for the fact that much of it has appeared elsewhere previously. While Mrs. King cannot be termed the Miss Gertrude Jekyll of America, she writes entertainingly for the amateur who contemplates making a small garden. Her enthusiasm, at times, seems to run away with her pen, and she becomes a trifle breathless, but there are many schemes and suggestions for garden making and planting which her transatlantic readers will, no doubt, find of interest. The book is well printed, and the half-tone illustrations and planting plans add to its value.

Dahlias and Gladioli.†

At first glance there would seem to be no particular reason why Dahlias and Gladioli should be combined to make a book, except that there is, perhaps, scarcely enough to be said about either (without shameless padding) to fill a saleable volume. Certainly the book now before us is of respectable size, though the price is rather high, probably on account of the twelve coloured plates with which it is adorned. Dahlias monopolise the better half of the book, and a Dahlia in colours enlivens the sober brown of the stiff linen cover. Until the last few years, the Dahlia suffered under a slight cloud of disapproval; growers disliked it for the tiresome habit of the flowers, which insisted on hanging their heads down and tucking them under the foliage; amateurs because they bore the reputation of being "earwiggy." Lately, largely due to the efforts of a few far-seeing growers, such as Cheal's on this side of the Channel, and Martin on the other, the Dahlia has left most of its defects behind, and—especially in "star" form—has forced its way to the hearts

of flower lovers and into the nurseries of every florist. Books about Dahlias are, however, still more or less of a rarity, and the present one, written by so good an authority as Herr Sandhack (who is in charge of the celebrated Schulenburg nursery in Gera) will be welcomed in many quarters.

Of the portion about Gladioli we can write with equal praise, and here it may truly be stated that Herr Sandhack is breaking new ground. The literature of the Gladiolus is very small indeed, and the present book, with its clear, lucid directions and excellent photographs (both black and white and coloured) and diagrams, makes a very welcome addition to the few volumes available for the guidance of the Gladiolus grower. In both parts of the book, pests and diseases come in for a good share of attention, and there are useful lists of varieties. So satisfactory, indeed, is the book that the lack of an index appears to be its only defect.

Roumania.*

THOUGH Mrs. Martineau's book* is mainly a chronicle of a visit she was privileged to pay to the late King Ferdinand of Roumania and his consort, who sought her advice and aid in the arrangement of the royal gardens, it would hardly be possible for the author to write a book without mention of flowers; so, interspersed with intimate sketches of the life of the Roumanian royal family at one or other of the residences, gardeners will find enough about the flora of the Carpathians to whet their appetite for a good deal more. Like the late King of Bulgaria, Ferdinand of Roumania knew the flora of his kingdom intimately. The author, therefore, had opportunities of seeing the wild flowers of the Carpathians under peculiarly favourable conditions, and was evidently struck by the wonderful colouring of the flowers. "Roumania is a land of Roses, the soil rich and deep, being the alluvial deposit of the Danube. The Roses, Paeonies and Irises grow to a size and possess a colour and scent impossible in any other country . . . whether it is due to the peculiar soil or not I do not know, but the Willow Gentian, which is generally of a slate blue colour in England, is of brilliant blue in Roumania, and all the flowers seem to be intensified in colour."

Roumania is clearly an earthly paradise of flowers, for when Mrs. Martineau proposed an herbaceous border in one of the royal gardens, she found nearly every flower she suggested vetoed because it was a wild flower in Roumania, "where you may see miles and miles of the purple *Salvia nemorosa virgata* and many another . . . Irises grow wild in quantities in the woods here, and many other flowers only seen in the herbaceous border in England, such as *Astrantias*, *Potentillas*, *Larkspurs* and *Campanulas*." And there is a wild Paeony of which we should like to know more, though we suspect it of being an old friend. "The flower is single, of a brilliant scarlet, and with a crown in the centre of bright yellow stamens." Mrs. Martineau's account of the flowers of Roumania should send many keen gardeners to that country next spring.

DWARF TREES IN THE ROCK GARDEN.

THE planting of dwarf trees, mostly of an evergreen character, serves a useful purpose in all extensive rock gardens, and probably the most popular subjects for the purpose are the dwarf Conifers. Such plants are considered to represent the dwarfed character of trees found growing in alpine altitudes; they serve also, to some extent, to relieve winter bareness and, finally, become good backgrounds for groups of choice flowering plants.

In a rock garden of large dimensions there is naturally room for trees which finally attain considerable size, but in the small rock garden it is important that the choice should be restricted to those species and varieties which

* *The Beginner's Garden*, by Mrs. Francis King (7s. 6d. net). Messrs. Charles Scribner's Sons, New York and London.

† *Dahlien und Gladiolen*. Von Herm. A. Sandhack. Berlin, Verlag Paul Parey, Hedemannstrasse, 10-11. Paper RM. 18, bound RM. 22.

* *Roumania and her Rulers*, by Mrs. Philip Martineau. Stanley Paul (1927). 10s. 6d. net.

are known to be of slow growth and more or less stunted habit.

But even some of these have a tendency to lose their dwarfness after a number of years, and become unsuitable. A variety of the common Spruce, *Picea excelsa prostrata*, for example, grows slowly at first, but after a period of ten or twelve years it has a tendency to make more rapid growth, and loses, to some extent, its prostrate habit. *P. e. globosa nana* is a good plant, making a rounded hummock of stunted growth, and *P. e. pygmaea* is a diminutive variety of pyramidal shape.

The Cypresses, generally, are too free-growing for this purpose, but *Cupressus obtusa* has two or three varieties of dwarf character which seldom reach more than two or three feet in height. *C. o. compacta*, *C. o. nana* and *C. o. pygmaea* are all good dwarf varieties of very slow growth, while *C. o. nana aurea* is a small, dense-growing plant with golden foliage. *C. pisifera* also has one or two coloured varieties of merit, notably *C. p. aurea nana*, with dense, rounded bushes of golden foliage, and *C. p. ericoides*, a greyish-leaved plant of more upright habit but restricted growth. Another grey-foliaged plant of considerable merit is *C. Lawsoniana Fletcheri*, which forms a pyramid of plumose habit and is slow-growing, while *Rheingold* is a variety that makes a small, dense bush and has attractive golden foliage.

There are one or two Pinuses of very dwarf habit which may be planted with effect in the rock garden, notably *P. Mughus nanus*, probably the dwarfiest of the mountain Pines, and *P. montana pumilio*, a small, dense bush.

Thuya occidentalis provides dwarf varieties in *globosa* which forms a dwarf, dense, globular bush, and *pygmaea*, a compact, miniature variety; while of *T. orientalis* the varieties *compacta* and *ericoides* are dwarf and slow-growing.

Among the Junipers there are several species and varieties admirably adapted to positions in the rock garden. *J. communis alpina*, the alpine Juniper, is of prostrate habit and seldom exceeds a foot in height. *J. Sabina* and several of its varieties are useful for planting where a low covering is needed, as also is *J. squamata*, the scaly-leaved Nepal Juniper. *J. communis fastigiata*—known as *hiernica*—is probably the neatest of all Conifers. It forms a slender, columnar tree, its numerous, rigid, close-set branches being clothed with short, deep-green leaves which give the plant a handsome appearance. *W. Auton.*

ALPINE GARDEN.

GYPSOPHILA FRATENSIS.

UNDER this name, a small plant that was put into cool, gritty soil, two years ago, now covers nearly a square yard with a close, dense carpet of its glaucous foliage. The trailing, perfectly prostrate stems seem to delight in draping the face of a sloping rock, but they will hang over a wall with equal good will. The flowers of *G. fratensis*, which appear from the later spring onwards, are borne on six-inch to eight-inch sprays, and they are a cheerful rose-pink, which is peculiarly in harmony with the bluish tint of the foliage. This alpine is quite hardy and wet, wintry weather does not seem to affect it. *A. T. J.*

ERINUS ALPINUS.

It may appear superfluous to write of the *Erinus*, but experience has taught me that it is often necessary to keep certain plants before the public, or they will not find their way into as many gardens as their merits would warrant. The little *Erinus* is one of those plants, and a few lines in its favour may be of service. To those who know it not it may be described as a little tufted plant only about six inches high, with small, neatly-formed leaves and heads of little flowers produced for a long time in

succession, beginning in spring and lasting for a long time. The flowers of the type are purplish, but there are rose, carmine, and white forms, seeds of some of which may be obtained separately.

In addition to *E. alpinus* there is another species named variously *E. hispanicus* and *E. hirsutus*, which is more densely covered with hairs and is of slightly taller and looser habit. The ideal place for these *Erinuses* is in the chinks of a wall, where it will spread and increase by self-sown seedlings. It does well in the crevices of rockwork also, but in some places dies off, when on the level, in a wet winter, but this is unusual. A big mass of it on an old wall looks delightful; and the writer still bears in his mind's eye the picture presented by an old, high wall by the sea in which an *Erinus* had been thoroughly established, and where there were myriads of the bright little flowers fully open, to the great adornment of the old, dark, sandstone structure. *S.*

reducing the colour of the flesh, there ought to be a moderate demand for the fruits, as there are many people who like to have things different from the majority.

Sops in Wine is usable from October to February. The tree is stated to be very hardy, vigorous and free-bearing. Dr. Hogg records that trees of this variety are not subject to canker. The experiences of growers in regard to this variety would be welcome. *C.*

HOME CORRESPONDENCE.

Birds and Fruit.—It is easy enough to see the damage done by tits to our best Apples and Pears; if it were not for muslin bags, or old muslin curtains cut into squares and tied on, I would not have an October or November

FIG. 255.—APPLE SOPS IN WINE.

FRUIT REGISTER.

APPLE SOPS IN WINE.

THIS very old Apple is known to most West Country people, and almost every cultivator of Apples must have seen it or heard about it. Nevertheless, it is a comparatively rare variety in gardens, and seldom makes an appearance at exhibitions. Its outstanding peculiarity is the deep red colour of the flesh, which, as the name suggests, looks as though it had been dipped in and had absorbed red wine. Well-grown fruits (Fig. 255) are of medium size, and the skin has varnished patches of deep crimson among the yellow and often russetted ground colour. The fruits are quite handsome when well-grown and well-coloured, and the flavour is pleasing, although by no means first-class when Cox's Orange Pippin is taken as the standard of flavour. At a recent meeting of the Royal Horticultural Society, Messrs. Stuart Low and Co. exhibited a few very fine specimens of this Apple, and these examples attracted a great deal of attention by reason of their colour and attractive appearance.

Whether a red-fleshed Apple of moderate flavour would ever become popular is a matter that only experience can decide. If Sops in Wine could be worked on a stock that would enhance its flavour and appearance, without

Pear or Apple that was not pecked. It is not so easy to see the good the tits do. Still, I am all for the tits. I put boxes in my fruit trees for them to nest in, and in the winter I carry Nuts in my pocket, which they gladly come and ask for; I have great tits, blue tits and cole tits. I know them all, and they know me. To watch them feeding their young is to get a faint idea of the amount of insect life they must destroy in the year; all day long the parents bring caterpillars and other things not so easy to recognise; I am glad to say they have to go to my neighbour's gardens for their provisions. The time I like best to see them is when the birds are busy amongst the blossoming trees; when I see them pecking at a bud I feel sure there is a grub there. I feel sure, but I cannot prove it; but such is my faith. Good luck to the tits. The more of them the better, but plenty of muslin bags must be put on when the choice Apples and Pears are ripening. *R. R. H. Moore, Painswick Lodge, Cheltenham.*

Lathyrus tuberosus, L.—When reading the pages of *The Gardeners' Chronicle*, I was pleased to notice the record of *Lathyrus tuberosus* for Gloucestershire. The plant is recorded as an alien in White's *Flora of Bristol*, but it appears to be known in many places in the Severn Valley, and Schoolbred included it from Lydney in his *Chepstow Flora*. Mr. Nicholson (*l. c.*) adds some other habitats, but I may state that

for some years it grew in a wild piece of ground amid the Chiltern Woods in Oxfordshire, near Pippard, and that last year I saw it as an alien at Burton-on-Trent, in Staffordshire. Once I got a labourer to dig me a root from the well-known Essex locality at Fyfield. I planted it in my garden, and the following year appeared the large Vetch *Vicia amoena* which I had never seen before! *G. Claridge Druce.*

Wild Birds and Garden Peas.—I recently published a letter in your esteemed contemporary *Country Life* (December 3) instancing a case where the theft of garden Peas was conclusively shown to be the work of the long-tailed field mouse, and one of your readers asks me to repeat the statement in your valuable paper. He writes: "I was told that the tits were eating my Peas, but, of course, did not for a moment believe it, but set three mouse traps (break-backs) in drain pipes. We caught eighteen long-tailed field mice and no more Peas were taken." I know of few birds that haunt our gardens in any numbers that do more good than the blue-tit and the great tit. Forty-five years ago, Yarrell stated that gardeners and others "see it (the blue-tit) busily at work on a fruit tree, bud after bud coming under its scrutiny, while the prospective covering of each drops on the ground and shows the destruction done. Content with such imperfect evidence, they go their way vowing vengeance on the blue cap. . . . Yet none can be more mistaken than these men." This statement is truer to-day than ever, for we now have detailed volumetric analyses of the stomach contents of large numbers of specimens, showing that only ten per cent. of the food of the two above-mentioned species is injurious, whilst of injurious insects they consume 78 per cent. and 66.5 per cent. respectively. Surely such friends are worthy of every protection. *Walter E. Collinge, The Yorkshire Museum, York.*

Culinary Peas and Superphosphates.—Mr. Copley advocates spreading superphosphate in the drills when seeds of culinary Peas are sown, but I cannot agree that this would be very beneficial to the growth of the seedling, because when seeds germinate the roots are very fine, therefore a dressing of superphosphate would be rather strong food. Mr. Copley also states that he is under the impression that superphosphate aids the formation of roots, but roots are formed by the plant to search for and absorb food, therefore, if the food is close at hand there is no need for foraging. I do not think superphosphate would encourage the formation of roots; indeed, roots are formed more freely in a poor soil than in a rich one. As the Pea is a very deep-rooting plant it would not get much—if any—benefit from the superphosphate when it is fully grown. I am inclined to agree with Mr. Roy that superphosphate should not be spread in the drills when sowing seeds of any kind. *Gavin Brown, Craig House Gardens, Montrose.*

—Without wishing to intervene between Mr. Copley and Mr. Grigor Roy, I may, perhaps, be permitted to state that while Mr. Roy is perfectly right in uttering a warning against bringing superphosphate into contact with certain vegetables, such as Peas, he is probably wrong in supposing that Potato sets are injured by it, certainly when mixed with sulphate of potash, as he rightly suggests. I have used this mixture, plus sulphate of ammonia, so many times on so many different soils for so many years without injury that I think he must be diagnosing his Potato trouble incorrectly. Whether Potato "seed" is cut or uncut (and even if it is cut to single eyes), it remains uninjured. So far from this invaluable chemical fertiliser being dangerous I think it is doubly beneficial, not only feeding the crop but repelling slugs. I think the proper plan, if the fertiliser is used at planting time, is to spread it in the freshly-opened drills and lay the Potatoes on it. Ground pests will not then attack them, while the food will quickly become available. I am glad Mr. Roy points out the difference of grade in superphosphates. I always use the thirty-five per cent. grade. *W. P. W.*

SOCIETIES.

ROYAL SCOTTISH ARBORICULTURAL. (ABERDEEN BRANCH.)

THE annual meeting of the members of the Aberdeen Branch of the Royal Scottish Arboricultural Society was held in Aberdeen on Saturday, 17th inst., Mr. John Michie, M.V.O., President, in the chair. The chief feature of the proceedings was a finely reasoned address by Mr. C. S. France, Aberdeen, on Forestry, Past and Present. A practical forester, now far advanced in years, Mr. France wholeheartedly devotes the evenings of his life to the welfare, interests and advancement of his beloved profession. He was one of the original founders of the Aberdeen branch, and read the first paper at the inaugural meeting in 1906, has been President of the branch, and an active member of the executive right from the start. He has had a wide experience of practical forestry in Scotland and in Ireland, and is most anxious that for the degree of B.Sc. in forestry it shall be essential to include practical training in the forests for one or two years.

Mr. France opened his address by saying he was not inclined to accept the sweeping assertion, so widely made, that forest management in the past had been neglected. He admitted that what was now designated the sylvicultural aspect of forestry was neglected, because the conditions and requirements of the past did not demand an advanced and economically sound system of forest management. Most of the forest lands were in the hands of private individuals and were afforested more for shelter and possibly for game coverts. The economic aspect was overlooked, except in some of the larger, wooded estates, where the profitable management of woodlands was not neglected. Forestry, he held, was dependent upon the necessities and requirements of the particular country. This was strikingly illustrated in Germany and France, where the most forest land was under national control. Under these conditions, so different from our own, it was necessary to systematise and methodise the conservation of wooded lands.

Proceeding, Mr. France admitted that the experience of recent years had revealed the fact that a different system of forest management is not only necessary but essential, and that, had more economic methods been adopted earlier, as well as an extended system of afforestation of waste land, we would have been in a much better position to-day. With all that, however, when they considered the huge amount of timber supplied by this country during the Great War, it had to be admitted that the hitherto arboricultural system of forestry had its merits, as well as its defects. He would place the renaissance of forestry in this country at about 1850. Since then, he contended, rapid strides had been made until the subject had now become quite an absorbing national question.

The speaker then proceeded to refer to the educational side of forestry, and pointed to what he considered a defect in the present system of forestry education in our universities. It was all very well to acquire a wide knowledge through excellent lectures in the class-rooms, but unless the student had acquired practical knowledge by personal training and work in the forest, he was only half a forester. It was not only necessary to know what was to be done in a given case, but to know how and when it should be done. Hence, he considered that one of the essential points in the examination for the B.Sc. degree in forestry should be a thorough, practical training of one or two years in the forest. In conclusion, Mr. France expressed his satisfaction at the prospect of a continuance in the work of forestry from a national point of view, but held it was necessary to guard against too hard-and-fast methods. Government, or semi-Government officers were liable to run into what might be called "red tape" methods of procedure, and thereby, in many cases, likely to do more harm than good. There must be a certain elasticity of operation if the work was to be sound. He

had no doubt these considerations had already had some attention from those responsible for the prosecution of this great national work.

The Chairman, in paying a warm compliment to Mr. France, for his shrewd and sensible comments, said he was in complete agreement with him about the Scottish woods, in particular, being originally planted for the benefit of game. In England, however, large plantations of Oak were laid down for the purposes of providing timber for naval construction. Those days were past and the English forests had gradually declined.

Professor A. W. Borthwick, of the Chair of Forestry at Aberdeen University, dealt with Mr. France's references to educational facilities. After paying a warm tribute to Mr. France and other pioneer, practical foresters, for the quiet but sound sylvicultural work they did in laying the foundations for the establishment of woods and forests—producing a quality of timber second to none—said he was sure that all engaged in the teaching of forestry were thoroughly agreed that the practical aspect must be linked up with the scientific and the theoretical aspects. Whatever was done elsewhere they had in Aberdeen a system of practical training. The students go out into the forests and plantations by arrangement with the Forestry Commission, and do the actual planting, surveying, and nursery operations at different seasons of the year. So far, therefore, as the practice of forestry could be taught in Scotland, they were taking full advantage of it. Theoretical and scientific forestry led to progress, of course, through research, and that, combined with practice, was the ideal. It is the intention concluded Professor Borthwick, to hold a summer school next June to enable apprentice foresters to learn the theoretical principles and foundations of scientific sylviculture, a linking up of the two educational systems which cannot fail to produce the best results. Professor Borthwick's intimation was very warmly applauded.

The meeting then proceeded to the election of office-bearers for the ensuing year, as follows: President, Mr. John Michie, M.V.O.; Vice-Presidents, Lord Forbes of Castle Forbes, Mr. S. J. Gammell of Countesswells, Major R. J. Nicol of Ballogie, and Provost Donald Munro, Banchory; Secretary and Treasurer, Mr. G. D. Massie, Aberdeen; Messrs. C. S. France, Neil McGregor and Charles Stewart were re-elected to the Committee, and Professor Borthwick was appointed to the vacancy in the Committee caused by the death of Mr. James Ward, forester, Keith. The proceedings concluded with the gratifying announcement made by the Chairman that the membership of the branch had increased during the year from 169 to 183.

Obituary.

William Landsborough.—The death is reported of Mr. William Landsborough, nurseryman, Kilmarnock, on Thursday, December 22, after an illness extending over the past two months. Deceased gained his experience at Ardwell, Kirkcudbrightshire, where he served his apprenticeship, and later at Newfield, Kilmarnock. After serving as head gardener on a Bearsden estate he returned to Kilmarnock, where he established a florist's and nurseryman's business over twenty years ago. In his earlier years he was a successful competitor at the leading horticultural shows, and although he took no active part in public affairs he was highly respected in the community.

TRADE NOTE.

PATENTS AND TRADE MARKS.—Any of our readers requiring information and advice respecting Patents, Trade Marks or Designs, should apply to Messrs. Rayner and Co., Patent Agents, of 5, Chancery Lane, London, who will give free advice to readers mentioning *The Gardeners' Chronicle*.

ANSWERS TO CORRESPONDENTS.

NAMES OF PLANTS.—J. B. *Euonymus japonicus* var. *albo-marginatus*. The different colouring of the young growth is quite a common occurrence.—H. E. 1, *Impatiens Sultanii*; 2, *Symphytum tuberosum*; 3, *Senecio laxifolius*; 4, *Pulmonaria saccharata*; 5, *Ligustrum sinense*; 6, *Leycesteria formosa*.

NAMES OF FRUIT.—W. L. 1, *Dumelow's Seedling*; 2, *Histon Favourite*.—F. A. A. 1, *Scarlet Nonpareil*; 2, *Sandringham*; 3, *Nonesuch*; 4, *Roundway's Magnum Bonum*; 5, *Blenheim Pippin*; 6, *Jolly Beggar*; 7, *Easter Pippin* (syn. *French Crab*); 8, *Dutch Codlin*; 9, *Small's Admirable*.—W. J. B. *Upham*. 1, *Court Pendu Plat*; 2, *Royal Russet*; 3, *Pile's Russet*.

NERINE BOWDENII.—M. A. It is quite an easy matter and well worth while to raise *Nerine Bowdenii* from seeds. These should be sown so soon as they are ripe, in a light, sandy compost. The seedlings grow quite well in an ordinary greenhouse, and should flower in about three years from seed-sowing.

NIGHT SOIL.—I. R. There is no modern book dealing with night soil and its uses, so far as we know. Most towns of any size, and even small ones, have sewage works nowadays, and human excreta goes down the sewers. All the same, you can make use of the supply you get, if you have a field or piece of ground at some distance from dwelling-houses, to avoid trouble with the inhabitants or local authorities. The best plan is to lay up long ridges of soil and hollow them out along the centre. Cross ridges should be made here and there to form the long trenches into compartments. Some sort of cart should be employed to convey the liquid and solid matter. This, backed close to the ridge, would allow the liquid to run into the trench by means of a sluice or wide spout. The solids can then be tipped into the trench. When one compartment is full, it could be deodorised by means of chloride of lime. When most of the liquid has sunk into the soil, each section of the trench should be covered over with a good layer of earth, after which little or no odour will be discernible, provided the material is not dropped about outside the trench. It should lie in the trenches for six months or more, after which the ridge could be turned over and the soil and night soil mixed together. By this time the materials will be solid, and will dry further by the turning. When digging or trenching is proceeding, a man may wheel a fair quantity to each trench, thus keeping the ground clean for those who are digging. This will make good manure for all the Cabbage tribe, Turnips, Onions, Leeks, Rhubarb, fruit trees and fruit bushes. Night soil is too rich in nitrogen to be used except in a small amount, or not at all, for Peas or Beans of any sort. The daily supply could be put in trenches as above stated. Iron tanks would soon rust, but zinc ones would be more durable. (2) *The Horticultural Note Book*, by J. C. Newsham, is obtainable (if not out of print) from Messrs. Crosby, Lockwood and Son, 7, Stationers' Hall Court, Ludgate Hill, London. They have many books on technical subjects, and you could communicate with them and let them know your wants. Try Messrs. L. Upcott Gill, Windsor House, Bream's Buildings, London, E.C.4, for the *Intensive Culture of Vegetables* (French System).

GARDENING APPOINTMENT.

Mr. William Stenhouse, who has been in charge of Messrs. SAMSON'S Nursery, at London Road, Kilmarnock, has taken up a similar position with Messrs. LAIRD and SINCLAIR, Dundee and Mifflin. He served his apprenticeship with Messrs. Dickson and Co., Edinburgh, and before going to Kilmarnock he gained a wide experience with several English firms, including Messrs. Paul and Son, Rose-growers.

MARKETS.

COVENT GARDEN, Wednesday, December 28th, 1927.

REMARKS.—Prices remain very firm throughout this department to-day. More Daffodils and Tulips are offered, but the supply of English Violets has been stopped by the severe weather. No French flowers arrived this morning.

GLASGOW.

Good business was transacted in the cut flower market in Christmas week, when buyers had to concede a material advance in prices. First consignments of Golden Spur Daffodils were disposed of at 3s. per bunch, while Mon Tresor Tulips ranged from 1s. 3d. to 1s. 9d. for 6's, and Le

Matelas from 1s. 6d. to 2s. Carnations were worth from 6s. to 12s. per dozen; pink Roses, 10s. to 18s.; and Lillium longiflorum, 7s. to 9s. per bunch. Narcissi varied from 2s. to 3s. per dozen bunches, despite the frosted condition of many blooms. Chrysanthemums were in good demand at about former prices; Phyllis Cooper realised 2s. 6d. to 3s. for 6's; Ada Brooker, Winter Cheer, Red Lincoln and Favourite, 2s. to 2s. 6d.; Mary Morris, 1s. 9d. to 2s. 3d.; W. Duckham, 1s. 9d. to 2s.; Niveus, 1s. to 1s. 6d.; Wilcox, 9d. to 1s. 2d.; and Heston White, 9d. to 1s.

Trade in the fruit market was none too brisk considering the season. The turnover in Apples gave no indication of expansion, but prices kept steady in spite of the plentiful supplies. Canadian Greenings made 34s. to 39s. per barrel; Spies, 40s.; York Imperials, 30s. to 32s.; Ben Davis, 20s. to 25s.; Baldwin, 26s. to 30s.; Oregon Pippins, 16s. to 20s. per case; Delicious, 13s. 6d. to 16s.; Winesap, 13s. 6d. to 14s. 6d.; Rome Beauty, 10s. to 11s. 6d.; Jonathan, 10s. 6d. to 15s.; Grimes' Golden, 12s. to 15s.; Jaffa Oranges, 14s. to 16s. 6d.; Valencia, unchanged; Mandarins, dearer, at 1s. 3d. to 2s. per tray; Grape Fruit, 22s.; Californian Winter Nelis Pears, 27s. 6d. per case; half-case, 15s. 6d.; Beurré Bosc, 18s. per box of 50 lbs.; Kippen Grapes, 3s. to 3s. 6d. per lb.; English Colmar, 1s. 6d. to 2s.; Belgian, 1s. 4d.; South African Peaches 12s. 6d. per box; and Apricots, 3s. per tray.

Tenerife Tomatoes improved at 22s. per bundle for best quality, and 14s. for ordinary; Lettuces, dearer at 4s. to 6s. per dozen; Cauliflowers, 4s. to 5s.; Mushrooms, 2s. to 2s. 6d. per lb. The market will be closed on Monday next, which is to be observed as New Year's Day holiday.

NEW HORTICULTURAL INVENTIONS.

THESE particulars of new Patents, of interest to readers, have been selected from the Official Journal of Patents, and are published by permission of the Controller of H.M. Stationery Office.

LATEST PATENT APPLICATIONS.
